Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., November 4, 1946.

The Secretary of Labor:

I have the honor to transmit herewith a report on the trend of urban wage rates in April 1946, which was prepared in the Bureau's Wage Analysis Branch under the direction of Frances Jones Clerc and Eleanor K. Buschman. Field work for the survey was conducted under the direction of the Bureau's regional wage analysts.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 891 of the

United States Bureau of Labor Statistics

[Reprinted from the MONTHLY LABOR REVIEW, November 1946.]

Trends in Urban Wage Rates, April 1946[1]

URBAN wage rates showed greater advances between October 1945 and April 1946 than in any 6-month period since the beginning of World War II, and at the end of August 1946 they were still registering substantial gains each month. Despite large increases in basic rates, however, real wages still showed only moderate advances over January 1941 levels, as a result of a 42.6-percent rise in consumers' prices between January 1941 and August 1946. If measured from wartime peak levels, real weekly earnings show a decline despite the basic wage rate increases that have occurred during the reconversion period, whereas real wage rates show a small gain.

These facts were disclosed by an analysis of the Bureau of Labor Statistics semiannual survey of the trend of urban wage rates for April 1946. The urban wage-rate series covers all manufacturing industries and the wholesale and retail trade, finance groups, local utilities, and service trades of the nonmanufacturing industries.

War and Postwar Wage Movements in Manufacturing

In April 1946, 8 months after the end of war with Japan, average hourly wage rates in urban manufacturing industry as a whole stood 11.7 percent above the VJ-day level, 12.4 percent above the VE-day level, and 48.9 percent above the rates that prevailed prior to the wartime wage rise, in January 1941 (table 1). Since April 1946,[2] wage rates have continued to advance at a rate of approximately 1 percent per month.

---

[1] For a more detailed description of the Bureau's measure of urban wage trends and the findings of previous surveys, see Monthly Labor Review, October 1944 (p. 684), or Serial No. R. 1684; February 1945 (p. 379), or Bulletin No. 809; September 1945 (p. 519), or Bulletin No. 846; and February 1946 (p. 289), or Bulletin No. 860.

Urban wage rate trends should not be confused with trends of factory earnings published in each issue of the Monthly Labor Review. The urban wage-rate series measures changes in basic wage rates resulting from general changes in pay scales and from individual wage-rate adjustments within occupational classifications. For incentive workers they reflect changes in straight-time hourly earnings of key occupational groups. They exclude the effect of such factors as the shifting of employment among regions, industries, and occupations, and most of the changes in the composition of the labor force, as well as changes in payments for overtime and late-shift work, vacations and holidays, and other similar items.

The series dealing with trends of factory earnings, on the other hand, is based on gross earnings of all wage earners and reflects such factors as hours of work, premium pay for overtime and late-shift work, and shifting of employment among regions, industries, and occupations. The estimated straight-time average hourly earnings are computed by applying a correction factor to gross average earnings to eliminate the effect of overtime premiums but not of night-shift premiums or other factors affecting gross earnings.

Urban wage rates showed moderate increases throughout the war. An advance of 17.0 percent in manufacturing industries occurred during the 21-month prestabilization period (January 1941 to October 1942). The subsequent period of wage stabilization (October 1942 to August 1945) witnessed gains in manufacturing wage rates averaging somewhat less than one-half of 1 percent per month and totaling 13.9 percent, bringing the total increase between January 1941 and the end of the war with Japan to 33.3 percent. Average weekly earnings in manufacturing rose more sharply, and reached a high point in January 1945, which was 78.3 percent above the January 1941 base period. This gain was the composite result of higher wage rates, a longer average workweek (by 16.4 percent), substantial amounts of premium pay for overtime and late-shift work, and the movement of large numbers of workers from lower-wage industries and areas to those where higher wages prevailed.

The months following January 1945, however, recorded a steady decline in weekly manufacturing earnings from the all-time high of that month, culminating in a sharp break in August 1945, coincident with the end of the war with Japan. This decline reflected the influence of the above-named factors (except wage-rate increases) operating in reverse while reconversion to a peacetime economy got under way.[3]

In the summer of 1945, organized labor began a concerted drive for increases in wage rates that would maintain wartime levels of earnings under a potentially shorter peacetime workweek. When wage controls were relaxed in August 1945, numerous employers immediately put into effect wage increases that were pending approval by the National War Labor Board; some gave raises that they had been prevented from granting during the period of wage stabilization; and still others allowed interim increases of small amounts which they intended to supplement after clarification of governmental wage policy and the establishment of wage-movement patterns for individual industries or areas. These types of increases accounted for most of the 1.7 percent rise in urban wage rates that occurred between August and October 1945.

---

[2] Estimate based on the Bureau's monthly series of average weekly hours and average hourly earnings. The latest data for the urban wage-rate series apply to April 1946.

The upward movement of wages since April 1946 is caused mainly by first or additional increases negotiated to bring the rates in specific establishments into line with industry or area patterns.

[3] See the Bureau's monthly series of Hours and Earnings, and of Employment and Pay Rolls, published monthly in mimeographed form and summarized in each issue of the Monthly Labor Review.

During the 6-month period following October 1945, pattern-setting wage negotiations of national importance were concluded, and increases in wage rates became general throughout the country. Some of these increases followed industry patterns, some followed area patterns, and a great many were modeled after the pattern of 18½ cents set in the 1946 steel case.[4] The net increase in urban wage rates between October 1945 and April 1946, chargeable in the main to these general wage changes, was 9.8 percent. More than half of this amount occurred after February 13, 1946, the closing date of the "wage increase pattern period" established by Executive Order No. 9697 of February 14, 1946. General wage increases between VJ-day and April 1946 brought the total of manufacturing wage changes resulting from this type of increase to 29.6 percent for the period since January 1, 1941.

Table 1 shows movements of wages in manufacturing, as indicated by various Bureau of Labor Statistics wage measures, for specified periods, January 1941 to April 1946.

TABLE 1.—*Comparative Summary of Changes in Earnings and Wage Rates in Manufacturing, January 1941–April 1946*

Period	Percent of change in specified period				
	Gross weekly earnings	Gross hourly earnings	Adjusted hourly earnings[1]	Urban wage rates	General wage changes
Total period (January 1941–April 1946)	+61.0	+54.9	+54.7	[2]+48.9	+29.6
Prestabilization period (January 1941–October 1942)	+46.0	+30.7	+21.5	[2]+17.0	+12.6
Stabilization period (October 1942–August 1945)	+7.3	+14.7	[3]+15.6	[2]+13.9	+3.6
October 1942–April 1943	+9.2	+5.7	+3.2	[2]+3.0	+1.1
April 1943–October 1943	+5.6	+4.7	+3.6	+3.8	+.5
October 1943–April 1944	+1.5	+2.5	+3.0	+1.9	+.5
April 1944–October 1944	+3.1	+1.8	+2.1	+2.2	+.4
October 1944–April 1945 (VE-day)	+.4	+1.3	+1.9	+1.6	+.5
April 1945–August 1945 (VJ-day)	−11.5	−1.9	[3]+.9	+.7	+.4
Postwar period (August 1945–April 1946)	+2.8	+3.3	[3]+10.1	[4]+11.7	[4]+11.1
August 1945–October 1945	−1.8	−3.8	[3]+1.0	[4]+1.7	[4]+1.5
October 1945–February 1946 (Executive Order No. 9697)	−1.0	+1.7	+4.2	+4.3	+4.1
February 1946–April 1946	+5.7	+5.6	+4.6	+5.3	+5.1

[1] Hourly earnings excluding premium payments for overtime, and with industries weighted in proportion to their 1941 employment.

[2] Partially estimated.

[3] Data not available for August 1945. July 1945 data substituted.

[4] October 1945 estimates revised on basis of more precise data obtained in connection with the April 1946 survey. Previously published October estimates were obtained from a survey of 18 of the 69 cities usually represented in the Bureau's indexes of urban wage rates.

MOVEMENTS OF GROSS AND REAL MANUFACTURING WAGES

Wartime trends.—Projecting the urban wage-rate index beyond April 1946 in the light of other wage measures for the same period, there appears to have been a further increase of 4 to 5 percent between

---

[4] For data on postwar general wage increases, see Postwar Increases in Basic Wage Rates, Monthly Labor Review, September 1946, or mimeographed Bureau press release, Increases Granted in Basic Rates Since VJ-day, dated September 20, 1946.

BUREAU OF LABOR STATISTICS

April and August 1946. Urban wage rates were, therefore, about 56 percent above prewar (January 1941) levels in August 1946. Average weekly earnings, which fell 14.6 percent between January 1945 and February 1946, began to rise again with increases in basic rates, and in August 1946 were 67.5 percent above January 1941 levels. The impact of the 42.6-percent rise in consumers' prices [5] over the same period reduced the increase in real weekly earnings to 17.5 percent, and in real wage rates to 9.4 percent (chart 1).[6]

Trends since wartime peak.—In comparing wage levels in August 1946 with peak wartime conditions (January 1945), wage rates increased an estimated 18.9 percent, but average weekly earnings stood 6.1 percent below the January 1945 base (chart 2). Adjusted by consumers' prices, the real earnings for these two measures of wages became a 5.1-percent advance and a 17.0-percent decline, respectively.

Trend of Manufacturing Wage Rates, April 1945 to April 1946

During the period of wartime wage stabilization, increases in wage rates as revealed by the urban wage-rate index, reflected not only general wage changes,[7] which usually accounted for only a small proportion of the increase, but also wage "adjustments" for individual workers, promotions of workers to the tops of job-rate ranges, hiring above normal entrance rates, and similar practices growing out of tight labor-market conditions. Since straight-time hourly earnings for incentive occupations are used in constructing the indexes, changes in productivity for these workers have also been reflected in the series. At the end of the war (VJ-day) urban wage rates had actually advanced 33.3 percent over the January 1941 level, but general wage changes accounted for an increase of only 16.7 percent (table 1).

By contrast with the war period, changes in wage rates since VJ-day may be identified very closely with general changes in wage scales. General wage changes amounted to an 11.1-percent increase in wage rates between August 18, 1945, and April 1946; the urban wage-rate index rose 11.7 percent.[8] The respective figures for the 1-year period covered by this study were 11.5 and 12.4 percent.

---

[5] As measured by the BLS index of consumers' prices. For an explanation of this index, see November 1946, Monthly Labor Review, p. 781.

[6] Real wages represent the purchasing power of actual wages. Real-wage indexes are computed by dividing actual-wage indexes by consumers' price indexes.

[7] The Bureau's definition of "general wage change," for purposes of these studies, is a general or across-the-board change in rates that affects, at one time, 10 percent or more employees, or all workers in important occupational classifications.

[8] See footnote 4.

CHANGES IN WAGE RATES IN INDUSTRY GROUPS

The trend of urban wage rates for major groups of manufacturing ndustries between January 1941 and April 1946 is presented in table 2. The change from VJ-day to April 1946 has not been separated or measurement at the industry-group level, but wage-rate changes etween April and August 1945 (as shown in table 1) were negligible n volume.[9]

Table 2.—*Percent of Change in Urban Wage Rates in Manufacturing, by Industry Group, January 1941–April 1946* [1]

Industry group	Percent of change from—								
	Jan 1941 to Oct 1942 [1]	Oct. 1942 to Apr. 1943 [1]	Apr. 1943 to Oct. 1943	Oct. 1943 to Apr. 1944	Apr. 1944 to Oct. 1944	Oct. 1944 to Apr. 1945	Apr. 1945 to Oct. 1945 [2]	Oct. 1945 to Apr. 1946	Jan. 1941 to Apr. 1946 [1]
All manufacturing industries	+17.0	+3.0	+3.8	+1.9	+2.2	+1.6	+2.4	+9.8	+48.9
Food and kindred products	+13.6	+3.6	+3.2	+1.1	+1.9	+1.4	+3.0	+7.8	+40.9
Tobacco manufactures	+15.7	+2.8	+1.1	+3.1	+1.7	+3.7	+5.3	+7.4	+47.8

Metalworking (except basic iron and steel and shipbuilding)	+16.2	+3.4	+5.4	+1.9	+2.0	+1.2	+2.0	+8.9	+47.9

[1] Data for periods prior to April 1943 are estimated.

[2] October 1945 estimates revised on basis of more precise data obtained in connection with the April 1946 survey. Previously published October estimates were obtained from a survey of 18 of the 69 cities usually represented in the Bureau's indexes of urban wage rates.

[3] Representation inadequate to show percent of change.

[4] Less than a tenth of 1 percent.

[5] Data not available.

[6] April 1945 to April 1946. Does not include the effect of 4-cent second shift and 6-cent third shift differentials introduced in 1945. The inclusion of shift differentials would bring the increase in urban wage rates between April 1945 and April 1946 to 15.4 percent.

[7] October 1943 to April 1946.

[8] April 1943 to April 1946.

The largest gains in rates for the 1-year period were made by petroleum (18.4 percent) and textiles (17.9 percent); the smallest gains[10] were in the food, shipbuilding, and the metal products industries other than basic iron and steel and shipbuilding (11.0, 10.4, and 11.1 percent, respectively). Including postwar gains as of April 1946, wage rates advanced after January 1941 by 70.5 percent and 65.6 percent, respectively, in the leather and leather products and the apparel industries. In view of the importance of piecework in these industries, these figures, to some extent, may reflect increased productivity. A similar increase in rates (63.1 percent) occurred in the textile industries. Rate advances in the metal products industries over the long period were slightly under the average for all manufacturing.

---

[9] General wage changes for the period ranged in volume from one-half of 1 percent for products of petroleum and coal to seven-tenths of 1 percent for furniture and finished lumber products.

[10] Relatively small gains were also made by the lumber, and the stone, clay, and glass-products industries, for which separate data are not published.

The postwar increase in wage rates shown by the urban wage rate index for manufacturing as a whole, as already noted, is almost the same as the increase from general wage changes alone. This also holds true for several of the individual industry groups, notably metal products, shipbuilding, rubber products, and petroleum. In other industries, the urban wage rate index shows an increase larger than the advance from general wage changes alone. On the other hand, part of the rise caused by general wage changes in basic iron and steel was offset by other factors, so that the full amount of the increase was not evident in the urban wage-rate index.

The variations that were found among industries in the postwar movement of wage rates were traceable to such factors as manpower shortages in low-wage consumer-goods industries, in which wage rates during the war had not increased proportionately with those of the war industries; changes in sex-composition of the labor force; [11] and increases in the proportion of all workers found in the lower range of rate brackets during the period of reconversion. Slackening of incentive earnings resulting from changes in products, materials shortages, and tightening of incentive standards was another factor affecting the trend of wage rates in some industries, although the consumer-goods industries, in which piecework is important, registered larger gains in the urban wage-rate index than the increases reported as general wage changes only. Had the index of urban wage rates in manufacturing been confined to time workers, the increase for manufacturing as a whole for the year April 1945 to April 1946 would have been approximately 1.5 percentage points greater than the increase for both time and incentive workers.

The upward trend of rates in individual industries during the year after VJ–day did not exactly follow the course of the increases granted in the major wage cases during the first months of 1946. In some industries, especially those which in previous months had been engaged in war production, the rise was substantially less than the amounts of the pattern-setting advances granted by major firms in the industry. In other industries, such as the textiles, the increases vere somewhat greater than the typical general wage changes during he period. Failure of the urban series to follow the publicized pat-ern-setting general wage increases results primarily from the inclusion n the index of plants which gave varying amounts of general wage aises, averaging on an industry-wide basis less than the amount of ncrease given in the pattern-setting cases.[12]

---

[11] Although constant weights for sex groups normally prevent this factor from influencing the urban wage-rate index, women workers have disappeared from some occupations in which they were found during the war, and the weights for them were consequently dropped. The effect of these changes on the index is believed to be only slight.

AREA COMPARISONS

The amount of postwar increase in manufacturing wage rates showed ome variation among individual cities or wage areas, but, in general, here was remarkable uniformity. Of the 15 major cities for which eparate postwar data can be presented (table 3), only 3 deviate more han 3 percentage points from the average advance for all manufac-uring. The largest gains were made in Portland, Oreg., and Hous-on, Tex.; wartime gains in both of these cities had been well below he national average. The smallest postwar rise in rates occurred in inneapolis. This city likewise had experienced relatively small war-

[12] See footnote 4, p. 3.

time wage increases in manufacturing industries. Its small postwar advance is attributable, at least in part, to reconversion problems in the metal-products industries, which employ a majority of the city's manufacturing workers.

Changes in Selected Nonmanufacturing Industries, April 1945 to April 1946

Urban wage rates in the nonmanufacturing industries covered by the survey advanced more evenly between April 1945 and April 1946 than in manufacturing, the 10-percent annual increase being almost equally divided between the two 6-month periods (table 4). In contrast, the greater portion of the 12.4-percent rise in manufacturing occurred during the period October 1945–April 1946, and much of it was concentrated around the precedent-setting wage increases of the first 3 months in 1946.

Table 4.—*Percent of Change in Urban Wage Rates in Selected Nonmanufacturing Industries, by Industry Group, April 1943–April 1946*

Retail trade	+9.2	+2.7	+5.7	+4.6	+5.5	+6.8	+39.7
Finance, insurance, and real estate	+3.9	+3.1	+1.6	+4.5	+1.7	+4.1	+20.3
Local utilities	+1.5	+1.1	+.3	+1.5	+2.3	+10.1	+17.6
Service trades	+6.4	+2.4	+5.4	+3.2	+2.8	+4.1	+26.9

[1] The specific industries selected to represent these groups in the measurement of wage-rate changes were as follows: *Wholesale trade*—general-line wholesale groceries; *retail trade*—department stores, clothing stores, and groceries; *finance, insurance, and real estate*—banks and savings and loan associations; *local utilities*—electric light and power or gas companies; *service trades*—hotels, power laundries, and auto-repair shops.

[2] October 1945 estimates were revised on basis of more precise data obtained in connection with the April 1946 survey. Previously published October estimates were obtained from a survey of 18 of the 69 cities usually represented in the Bureau's indexes of urban wage rates.

Type of wage-rate changes.—The increases in nonmanufacturing industry wages were largely the result of wage adjustments for individual workers rather than of general or across-the-board wage increases, such as occurred in manufacturing. In the period between August 18, 1945, and April 1946, for example, an estimated 41 percent of all the workers in the selected nonmanufacturing industries received general wage increases, whereas about 79 percent of all manufacturing workers were given such raises.[13] Nevertheless, the over-all increase in nonmanufacturing rates between April 1945 and April 1946 was only 2.4 percentage points less than the increase in manufacturing.

WAGE INCREASES IN INDIVIDUAL INDUSTRIES

Local utilities and retail trade made the greatest advances in rates during the 1-year period of all the five nonmanufacturing industry groups studied. Moreover, the gains registered by them (12.6 and 12.7 percent, respectively) compared more favorably with gains in manufacturing industries than did the increases in the finance industries, the service trades, and wholesale trade, which were all less than 10 percent (table 4).

Only the utilities group had received general or across-the-board increases in rate scales that approximated the advance in the urban wage-rate index. More than 95 percent of the workers in this group are estimated to have benefited from general wage increases following VJ-day, as contrasted with about half of the employees in wholesale trade and approximately one-third in retail trade, the service trades, and the finance group.[13]

AREA COMPARISONS

The nonmanufacturing urban wage-rate indexes of individual wage areas showed a great deal of variation in amounts of increase, ranging from 4.7 percent (in Cleveland) to 18.3 percent (in Minneapolis) between April 1945 and April 1946 (table 5). In 9 of the 15 cities for which separate data can be shown, rates had advanced by more than the national average, and these include such widely separated areas as Providence, New Orleans, Baltimore, and Buffalo. Among the cities showing lower-than-average increases are New York City, Cleveland, Houston, and Portland, Oreg.

These variations cannot be ascribed to differences in industrial composition of the city indexes, as the nonmanufacturing indexes, unlike manufacturing indexes, represent the same industries in all cities. Individual city trends in nonmanufacturing wage rates during the past year apparently have been influenced by such factors as labor supply and the size of wartime wage increases.

LETTER OF TRANSMITTAL

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., October 17, 1946.

The Secretary of Labor:

I have the honor to transmit herewith a report on employment outlook for business machine servicemen. This is one of a series of occupational studies prepared in the Bureau's Occupational Outlook Division for use in vocational counseling of veterans, young people in schools, and others considering the choice of an occupation. The present study was prepared by Claire L. Labbie, under the supervision of Richard H. Lewis. The Bureau wishes to acknowledge the cooperation received from companies and trade associations in the business machine servicing field.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

EMPLOYMENT OUTLOOK FOR BUSINESS MACHINE SERVICEMEN

Introduction

About 20,000 men have the important job of keeping in good running condition the machines hat millions of office and store workers use in their work. Business-machine servicing is not a large ield, but one of interest to young men with mehanical aptitudes because it offers opportunity for a limited number to enter in the next few years with the prospect of steady employment for a long period.

Business machines have changed the way most ffice jobs are done, have created new types of jobs, and have made possible the great increase in the olume and scope of correspondence, accounting, tatistics, and general clerical work that has ocurred in recent years. In a few decades they have ecome essential for the efficient operation of all ypes of business offices and stores. The typewriter has eliminated the old time penman who aboriously and slowly copied letters and records by longhand. Instead of many bookkeepers painstakingly making entries on ledger sheets, we find in large modern offices workers operating machines which post and compute accounting records in a single operation. Busy executives save time by dictating to machines instead of stenographers; clerks in stores handle sales transactions with greater speed and accuracy with cash registers; and duplicating machines make possible the speedy and economical production of copies of special notices, bulletins, and advertising leaflets. Punched card accounting-statistical machines rapidly sort record cards, make computations, add up the results, and print the answers.

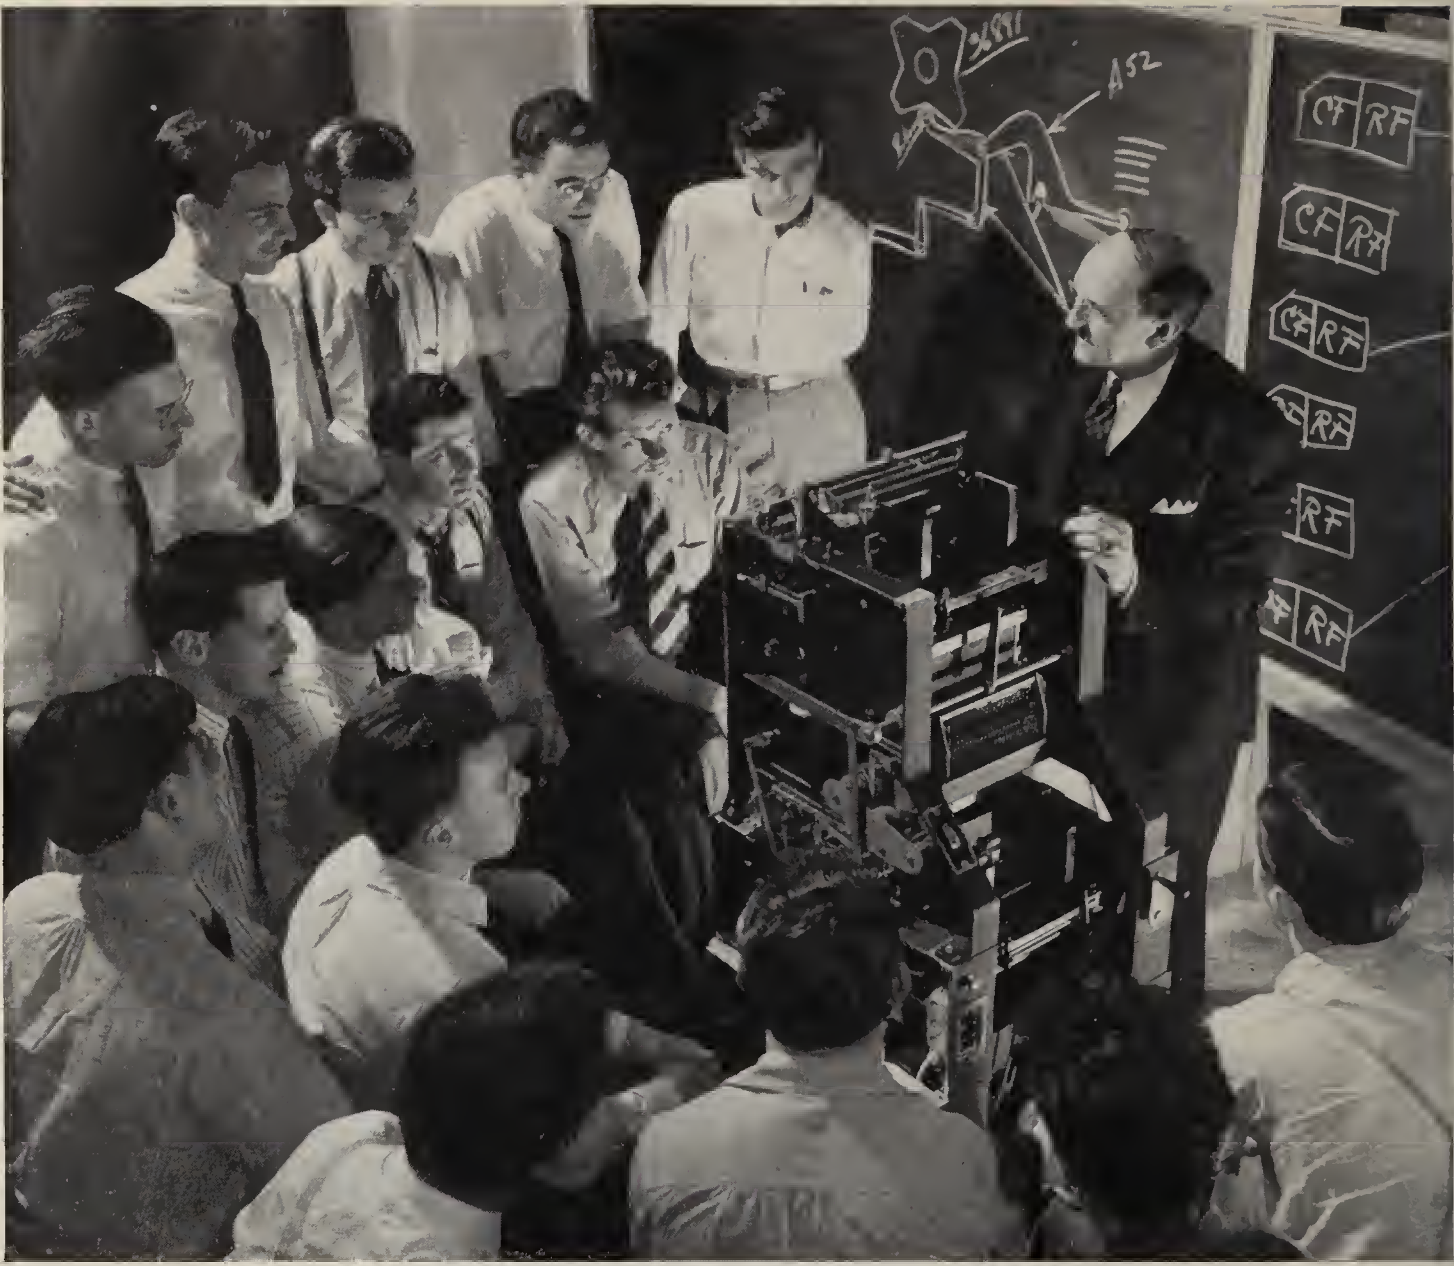
The widespread use of these machines is fairly recent. Most of the growth has occurred in the past 3 decades along with the general increase of clerical and accounting work. This trend is shown by the increase in the number of clerical and related workers from less than 4,000,000 in 1910 to almost 9,000,000 in 1940.

The Work of Business Machine Servicemen

Duties

The most important business machines, in terms of the number of jobs they provide for servicemen, are typewriters, adding machines, calculators, cash registers, accounting-bookkeeping machines, punched card accounting-statistical machines, dictating and transcribing machines, and the various duplicating machines. There are in addition many other kinds of business machines, including equipment for handling checks, coins, currency, and envelopes; autographic registers; time recording machines; postage meters; and microfilm machines. Although there are a small number of men who repair as many as four or five different types of machines, most servicemen specialize in repairing one or two types.

Business machine servicemen must know thoroughly the mechanism of their respective types of machines. They inspect and take apart appliances to find defects; adjust the various parts of the machines, using such common hand tools as wrenches and pliers, and special tools designed for the particular type of machine; repair or replace broken or worn parts; and clean and oil machines. Sometimes they are required to explain to operators how the machines work and how to avoid damaging them. Minor adjustments are usually made in the offices where the machines are used; all other work is performed in the repair shop. In some shops, the servicemen specialize in working either "outside" or "inside" the shop.



Class in repair of punched-card accounting machines.

Training

In general, the way to learn this work is to be hired as a trainee in an office machine repair shop. The beginner is paid a salary while he is working and receiving instruction. Training may be given on the job, through courses in a company school, or through a combination of both of these methods. The length of this training varies greatly, depending upon the types of equipment serviced, the number of different brands repaired, and the kind of shop in which employed. Training in independent shops tends to be somewhat longer than in manufacturers' service branches, because of the greater variety of the work in independent shops and the more informal nature of much of the instruction. A few schools have recently been opened to give instruction in business machine servicing, covering mainly typewriter repair. Because this is a new development it is not known at this time if their graduates will qualify as skilled mechanics when they seek employment, or to what extent their training time on the job would be reduced.

The Federal Committee on Apprenticeship has approved a 2-year training program for "business machine mechanics" with the requirement that the apprentices' training include the repair of several ypes of appliances and various makes of each type.

The main aptitudes needed by a trainee are general mechanical ability and manual dexterity. The work is relatively light, except for the occasional lifting of appliances; in general, physical demands are not high. Nevertheless, very few women are employed, this being almost entirely a man's occupation.

Chances for Advancement

Business machine servicemen may be promoted o supervisory jobs, such as that of service manager n a local service branch. Some may become salesmen of the equipment which they have repaired and, as salesmen, generally earn much more than repairmen. Experienced men sometimes open their own independent repair shops.

Working Conditions

Repairing business machines is comparatively free from the danger of accident and is cleaner than most mechanical trades.

Very few business machine repairmen are members of unions. Most of those who are members, however, belong to the International Association of Machinists, the United Electrical, Radio and Machine Workers of America (CIO), or to small independent unions.

The amount of work does not vary much from season to season, and most servicemen are employed the year round.

Where Employed

Business machine repairmen are employed mainly in the local service branches of companies which make the machines. These service branches are operated in connection with the sales offices of the firms. Repairmen in service branches repair, and are trained on, only the company's own make of machine. A large proportion of typewriter and adding machine servicemen, however, work in independently owned local repair shops. Most of these independent shops have only a few employees who usually service all make of typewriters and adding machines. Another source of employment is found in Federal, State, and local governments. In the Federal Government, men repair mainly typewriters, adding machines, and calculators. Applicants for Federal employment must have had at least 3 years' experience in servicing at least one type of office machine. The basic entrance salary for office appliance repairmen in the Federal Government is $2,243 a year.

Servicemen are employed principally in the large cities, since this is where the bulk of office machines are used. In small cities and in towns most of the work is done by independent repair shops, many of which are dealers for the manufacturing companies.

General Employment Outlook

In the next several years, although no sharp increases in employment are expected, there will be some opportunities for new workers to get into most of the different types of business-machine servicing jobs. Looking further into the future, the prospects are for a gradual rise in the employment of business-machine servicemen. During the past 30 years, the increase in the volume of record keeping and general clerical work, a desire to increase efficiency of office work and reduce labor costs, and the development and introduction of new types of machines have caused a steady growth in the use of business machines of all kinds. This trend should continue, and, particularly for certain types of business machines, there are many places where new installation of machines can improve efficiency and reduce costs.

During the war, the production of business machines for civilian use was drastically curtailed. Although manufacture has been resumed there is still a large accumulated demand which will take several years to fill. Much of the demand is for replacement of existing machines, but the machines in use should be increased substantially beyond the present number. The eventual effect of this increase will be to require more servicemen to keep the business machines functioning efficiently.

The general upward trend of employment in this occupation is significant in considering the long-run opportunities, but also important is the relative stability shown. In prosperous periods additional machines are put in use, thus adding to the need for repairmen. In less favorable times, sales of new machines usually fall; but, since this means that the machines are used longer than would normally be the case, there is continued need for maintenance work. The result has been that employment of servicemen has held up relatively well in periods of depression. Men who establish themselves in this field, particularly if employed by the large national concerns, are fairly well assured of continuing employment for many years if their work is satisfactory.

The employment opportunities, training requirements, and earnings in each major type of business machine servicing job are discussed below. It should be realized that in each case the description of opportunities refers to the conditions in the country generally, and that individual companies and particular localities may vary in the opportunities afforded for employment of new workers.

Employment Opportunities in Individual Occupations

Typewriter Servicemen

Typewriters are the most widely used of the business machines, having an important place in almost every type of office. In addition, many typewriters are used by individuals in their homes, which is not the case with other business machines. Typewriter servicing is the largest office machine repair occupation, with approximately 8,000 typewriter mechanics employed at the present time to maintain the millions of typewriters now in use.

A 2- to 3-year period of on-the-job training is ordinarily necessary to become a skilled typewriter repairman. During this training period, the mechanic learns how typewriters work and is taught how to clean the machine and to make all kinds of repairs, including aligning (making type print evenly), fixing the escapement (spacer), and adjusting the shift mechanism and ribbon movement.

During the war, while typewriter manufacturing was curtailed, there was an increased need for servicemen to keep existing typewriters in good working condition and to replace those machanics going into the armed forces. Despite this situation relatively few workers were trained during this period—owing to the drain of young men to the armed forces, the wartime labor shortage, and the reluctance of many shops to take on trainees—and a shortage of skilled men resulted. This shortage has continued, and demand has been only partly met by veterans skilled in typewriter repair work returning to the trade. Thus, there should be opportunities for a small number of newcomers to get jobs as trainees in the next several years. In some areas, particularly in the smaller towns, there are also opportunities for experienced and skilled typewriter servicemen, with general business and sales ability, to open their own repair and sales shops. In the longer run, employment in this field will tend to rise as the use of typewriters gradually increases, particularly in homes and schools.

In 1945 the typical pay of experienced typewriter servicemen for a 40-hour week was between $40 and $65 in the larger cities. This represents an increase over prewar earnings. Because they are required to work on various makes of typewriters, servicemen employed in independent repair shops usually earn more than men in the service branches of manufacturing companies. There are no figures on the earnings of the men who run their own repair shops. The profits of these shops vary widely and are influenced by such factors as the size of the firm and its location.

Adding-Machine Servicemen

Adding-machine repair requires less skill than most of the major business machine servicing occupations. Consequently the training period is relatively short, 6 months to a year of on-the-job instruction usually being all that is needed to learn the repair of a single make of adding machine. However, for those who learn to repair several makes of adding machines a longer training period is necessary. Very often, the servicing of adding machines is combined with typewriter repair or calculator repair into a single job.

Employment prospects for adding-machine repairmen are about the same as for typewriter mechanics. The actual number of new openings, however, will be far fewer for adding-machine mechanics, as there are four times as many men servicing typewriters as repairing adding machines. About 1,800 men now have jobs in which most of their time is spent in adding machine repair, in addition to the large number who repair adding machines part time along with other business machines.

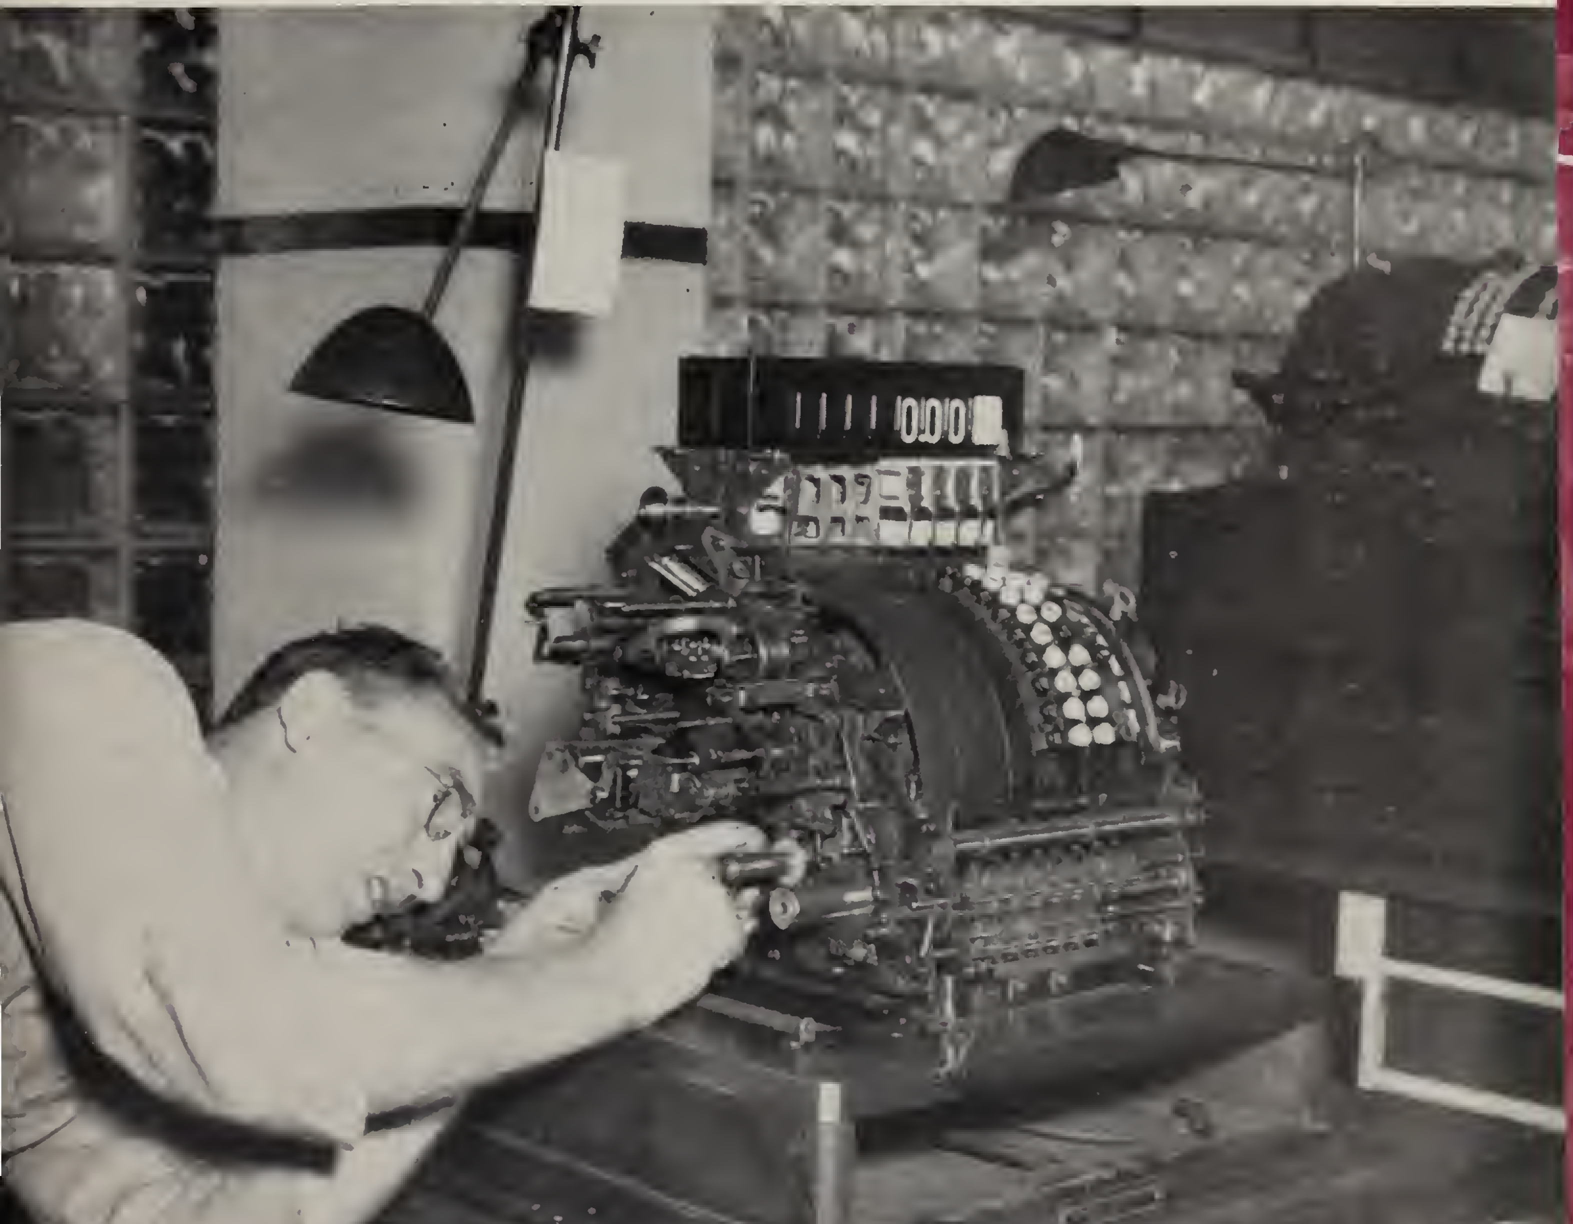
In 1945, typical weekly salaries of experienced adding-machine servicemen were between $40 and $60 in large cities. This is substantially higher than their prewar earnings.

Cash Register Servicemen

Next to typewriters, cash registers are the most widely used business machines. They are found mainly in retail stores and service establishments. Cash registers vary greatly in the number of things they can do. The simple models merely record each transaction, total the day's receipts, and provide a change drawer. The more complicated cash registers tabulate several different kinds of information on one transaction simultaneously, such as identification of clerk, department, and type of merchandise, as well as provide printed receipts with such information for the customer. The more elaborate cash registers actually perform many functions of accounting machines.

Nearly all cash register repairmen are trained in and employed by the service branches of the one

Repairing a cash register—Usually done in service branch of principal manufacturer.



company which manufactures the great majority of cash registers. Training for this work consists of 1 year of on-the-job instruction followed by about 6 months at the company school. In addition, a brief learning period in adding-machine repair may also be provided, since cash register servicemen in some cases also work on adding machines.

During the next few years there will probably be more cash registers in use than ever before, since retail trade is expected to expand. This will mean an increased demand for cash register repairmen. Thus, prospects are favorable for entry into this field, although the number of men who can enter in any one year is limited by the small size of the occupation. At the present time there are probably not more than 1,600 cash register repairmen in the United States.

Prewar average weekly earnings of cash register servicemen were from $35 to $50 in the larger cities. During the war these workers averaged between $50 and $75 a week.

Calculator Servicemen

Calculating machines, which add, subtract, divide, multiply, and also perform combinations of these operations, are used mostly in offices where a great many computations are necessary. These machines, most of which are electrically operated, have elaborate mechanisms, and, therefore, skilled men are required to repair them. This is a fairly small field of work, with about 2,000 employed at the present time.

To become a calculating machine repairman it is necessary to have 1 to 2 years of on-the-job training, often combined with 3 or 4 months of instruction at a company school. In the next several years there will be openings for only a very limited number of calculating machine servicemen. The shortage of these men during the past few years was caused primarily by their entrance into the armed forces. The return of these mechanics to their former jobs limits the number of beginners needed in the next several years. After the temporary period of adjustment is over a continued gradual expansion in the use of calculators should create some additional servicing jobs and insure steady employment for those in the trade.

In 1945, typical weekly earnings of experienced calculating machine servicemen in the large cities were from $45 to $65.

Accounting-Bookkeeping Machine Servicemen

Accounting-bookkeeping machines vary greatly in function. Some machines only post entries, some do billing, while others are combination typewriter and computing devices. All types have keyboards, like typewriters and adding machines, and are operated by striking the proper keys. They should not be confused with the punched card accounting-statistical machines which are described in another section. Accounting-bookkeeping machines are used wherever a great deal of accounting and bookkeeping is done, such as in department stores, retail and wholesale businesses, and banks. Since there are several different types of machines, each quite complicated, the servicing is highly skilled work. About 1,000 men are now employed in this work.

Usually a man must have had 1 or 2 years' experience as an adding machine, calculator, or cash register repairman in order to be eligible for accounting-bookkeeping machine training—which consists of 2 to 3 years of on-the-job instruction and, in some cases, an additional 6 months of training at a company school. In at least one major office machine appliance firm, however, this work is combined with the servicing of other office machines, and a total of 4 or 5 years' training is required.

Many veterans skilled as accounting-bookkeeping machine repairmen have returned to their former jobs, but there are not enough of them to meet the need resulting from the curtailment of training during the war. Thus, there will be jobs for trainees. These openings will be filled, however, by men who have had the required background in servicing adding machines, calculators, or cash registers. It will be several years before men not having this background can get the experience to qualify for jobs as trainees. By that time there will be fewer openings than at present, although the growth in the use of these machines and the need to replace men who leave the occupation will provide opportunities for a small number of beginners each year.

In 1945, typical weekly earnings of experienced accounting-bookkeeping machine servicemen in the large cities were from $65 to $85, excluding overtime—substantially higher than their prewar earnings of between $40 and $65 a week.

Accounting-Statistical Machine Servicemen

Most amazing of the business appliances are the punched card accounting-statistical machines. Great masses of accounting and statistical data may be recorded, tabulated, and analyzed with this equipment. The information is punched on cards alphabetically or according to a code, and the cards are put into machines which sort them and tabulate the results. Besides the basic card punching, sorting, and tabulating machines, many other machines are used, such as collators, verifiers, and multipliers and dividers, each having its own specific purpose. These machines are used mainly in large organizations, such as government agencies, department stores, insurance companies, and large industrial establishments for pay-roll and other accounting records, inventory control, statistical surveys, and similar purposes.

The servicemen are employed solely by the two firms which manufacture and service all punched card accounting-statistical machines. These men may be assigned to work anywhere in the United States. They rarely transfer from one company to the other. High school graduation, followed by about 2 years of technical schooling in electrical or mechanical engineering is a necessary qualification for this work. However, the equivalent in practical experience may be substituted. After a 2-month on-the-job trial period, new men are given 3 to 4 months' instruction at a company school. They then work under experienced repairmen until they are able to service machines on their own.

For many years in the future there will be continued growth in the use of punched card accounting-statistical machines. This growth, together with the need for replacing those who leave this work, means that prospects should be favorable for entering the occupation and remaining employed in it for many years. The number of men that will be hired in any one year will be limited, however, by the small size of the occupation—there are about 2,400 punched card accounting-statistical machine servicemen employed at the present time—and by the fact that increases in use of the machines will be gradual rather than sharp. In recent months, there have been practically no openings for beginners in the company employing the majority of servicemen, because of the large number of experienced veterans returning to their jobs with the firm. This company expects, however, to resume the hiring of new men for this work within the next year. The other company in the field is currently hiring men for trainee jobs.

The entrance salary for punched card accounting-statistical machine servicemen is about $35 per week. After completing the first 6 months of training they earn about $40. Periodic pay increases are given thereafter, according to skill and experience.

Dictating Machine Servicemen

The widespread use of dictating and transcribing machines is a relatively recent development. There are now about 1,000 skilled men employed in servicing this equipment. At present, however, the application of electronic principles and the use of electronic tubes is changing considerably the nature of the dictating and transcribing machines being manufactured. This shift, from an acoustic machine to an electronic one, affects the servicing of the equipment and hence, to some extent, the qualifications and training needed. Although the introduction of electronic machines means that the servicemen must have additional knowledge, the electronic features require far less servicing than the mechanical features.

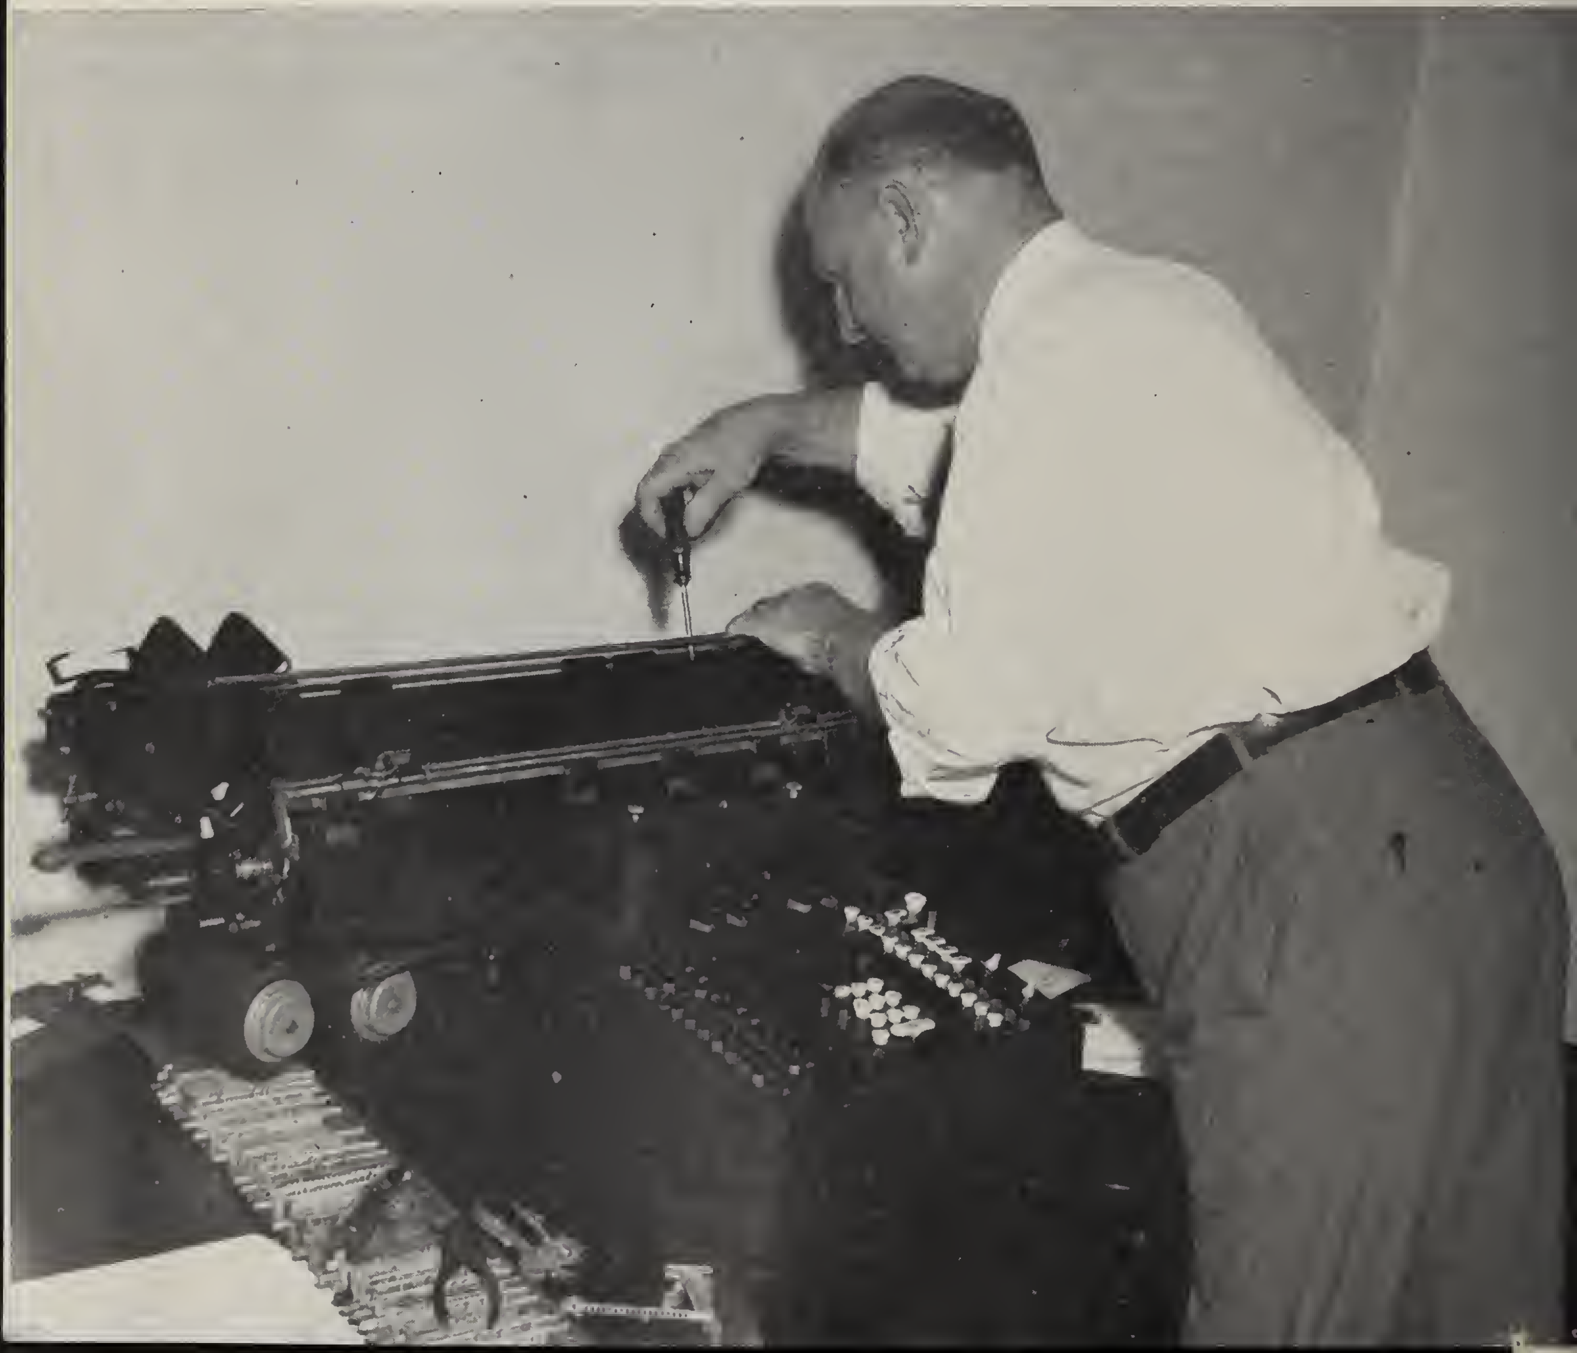
Cleaning a calculator with a fine spray of cleaning fluid—An important step in keeping the complicated mechanism in good running condition.

At least 1 year of technical training in electricity and electronics, or equivalent knowledge, is now required before entering employment. The length of the subsequent training varies considerably among the companies in the field. Two of the important firms require 6 months to a year of on-the-job training, often combined with instruction by visiting teachers; in another company, 2 to 3 weeks of instruction at the factory school is the only training given. Returning veterans who are experienced in servicing acoustic dictating and transcription machines usually need additional training on the electronic machines. The length of this added training depends upon the man's background in electricity and electronics.

Dictating machine repairmen are employed mainly in cities and large towns either by the service branches of the firms manufacturing this equipment or by their distributors. In the small towns, typewriter and adding machine mechanics often learn to service the acoustic dictating and transcribing machines. However, because these men lack the necessary electronic background, they will be unable to repair the electronic machines.

In the next year or two, job opportunities for beginners will vary among the major companies

Repairing an accounting-bookkeeping machine—One of the most highly paid of business machine servicing jobs.



mploying dictating machine servicemen. Some ompanies will have openings for new men; others lready have enough experienced workers to meet heir immediate needs. However, in the years head, there will probably be far more dictating nd transcribing machines in use than there are at resent. This expansion will create additional ervicing jobs and will also provide steady employnent for men already trained in the work. The ccupation is small, nevertheless, and the number f new openings in any one year will be limited. Ioreover, some of the servicing of electronic dicating and transcribing machines may be done by adio repairmen, who can in a few months learn to ervice this equipment. In the future there may e widespread application of wire recording to dicating and transcribing appliances. If this should appen, more of the repair of these machines would e done by men trained as radio servicemen.

In 1945, typical weekly earnings of experienced lictating machine servicemen in the large cities vere from $40 to $50.

Duplicating Machine Servicemen

There are five main types of duplicating mahines used in offices—direct, gelatin hektograph, pirit, offset, and stencil. These machines vary n the way they operate, but they are all used for he same purpose, which is the speedy and economcal production of advertising leaflets, special noices, instruction manuals, press releases, and imilar materials.

Duplicating machine repair is the least skilled of the office machine servicing occupations, and consequently requires the shortest training period. The length of this training varies somewhat with the type of duplicating appliance to be repaired. For stencil and gelatin hektograph equipment, less training is needed than for the other types. In general, however, to learn duplicating machine repair requires from 3 to 6 weeks at a company school plus about 3 or 4 months of on-the-job training. A repairman learns to service all the machines manufactured by his company. In order to transfer to a firm making a different type of duplicator, almost complete retraining is required.

Duplicating machine repairmen are employed either by the service branches of companies manufacturing these appliances or by their dealers. They may work in any sizable city or town throughout the country.

At the present time there are about 1,300 workers employed in this occupation. During the next year or two there will be few openings for newcomers, because experienced veterans returning to their former jobs, plus those trained as replacements during the war, will fill nearly all employment requirements. Thereafter, because of normal replacement needs, the hiring of a small number of men annually will be resumed.

In 1945 typical earnings of experienced duplicating machine servicemen were between $40 and $55 a week in the larger cities.

How to Get More Information About Job Opportunities in the Field

Men interested in becoming office machine mechanics may find out what job openings are available in several ways. The classified section of the local telephone book lists independent repair shops and the service branches of manufacturing companies. The national office of firms manufacturing these appliances can furnish the addresses of their service branches.

The major companies manufacturing and servicing dictating and transcribing machines are:

Dictaphone Corp., 420 Lexington Ave., New York, N. Y.
Thomas A. Edison, Inc., Ediphone Division, West Orange, N. J.
Soundscriber Corp., 146 Munson St., New Haven 4, Conn.

There are a large number of companies manufacturing duplicating machines. A few of the more well-known firms are:

Addressograph-Multigraph Corp., 1200 Babbitt Rd., Cleveland. Ohio.
A. B. Dick Co., 720 West Jackson Blvd., Chicago 6, Ill. (makers of "Mimeograph" equipment).
Ditto, Inc., Harrison at Oakley Blvd., Chicago 12, Ill.

Major manufacturers of other types of business machines with Nationwide service branches are listed in the appendix table.

Those interested in working for independent repair shops may write to the National Office Machine Dealers Association, 818 Winters Bank Bldg., Dayton, Ohio, for the names of firms in their home town. The local office of the United States Employment Service should also be consulted. Veterans may get information, especially about Government financial aid while training, at the nearest Veterans Information Center.

Occupational Outlook Publications of the Bureau of Labor Statistics

This bulletin is one of a series of reports on employment trends and opportunities in the various occupations and professions, for use in the vocational guidance of veterans, young people in schools, and others considering the choice of an occupation. The reports describe the long-run outlook for employment in each occupation and give information on earnings, working conditions, and the training required.

Reports are usually first published in the Monthly Labor Review (subscription price per year, $3.50) and are reprinted as bulletins. Both the Monthly Labor Review and the bulletins may be purchased from the Superintendent of Documents, Washington 25, D. C.

Employment Opportunities for Diesel-Engine Mechanics.
Bulletin No. 813 (1945), price 5 cents. (Monthly Labor Review, February 1945.)

Occupational Data for Counselors: A Handbook of Census Information Selected for Use in Guidance.
Bulletin No. 817 (1945), price 10 cents. (Prepared jointly with the U. S. Office of Education.)

Employment Opportunities in Aviation Occupations, Part 1.—Postwar Employment Outlook.
Bulletin No. 837–1 (1945), price 10 cents. (Monthly Labor Review, April and June 1945.)

Employment Opportunities in Aviation Occupations, Part 2.—Duties, Qualifications, Earnings, and Working Conditions.
Bulletin No. 837–2 (1946), price 20 cents. (Monthly Labor Review, August 1946.)

Employment Outlook for Automobile Mechanics.
Bulletin No. 842 (1945), price 10 cents. (Monthly Labor Review, February 1946.)

Employment Opportunities for Welders.
Bulletin No. 844 (1946), price 10 cents. (Monthly Labor Review, September 1945.)

Postwar Outlook for Physicians.
Bulletin No. 863 (1946), price 10 cents. (Monthly Labor Review, December 1945.)

Employment Outlook in Foundry Occupations.
Bulletin No. 880 (1946), price 15 cents. (Monthly Labor Review, December 1945 and April 1946.)

Factors Affecting Earnings in Chemistry and Chemical Engineering.
Bulletin No. 881 (1946), price 10 cents. (Monthly Labor Review, June 1946.)

Employment Outlook in Machine Shop Occupations.
Bulletin No. 895 (1947). (In press.)

Washington 25, D. C. - Price 15 cents

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., March 4, 1947.

The Secretary of Labor:

I have the honor of transmitting herewith a bulletin presenting the results of a study of State and regional variations in prospective labor supply. The information presented here should prove helpful to labor, business, and government groups concerned with problems of employment, industrial location, marketing, housing, and social security.

The study was prepared by Lester M. Pearlman and Leonard Eskin in the Bureau's Occupational Outlook Division. Sophia C. Mendelsohn and Mary J. Levy assisted in the formulation of the estimating procedures and supervised the statistical operations.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 893 of the

United States Bureau of Labor Statistics

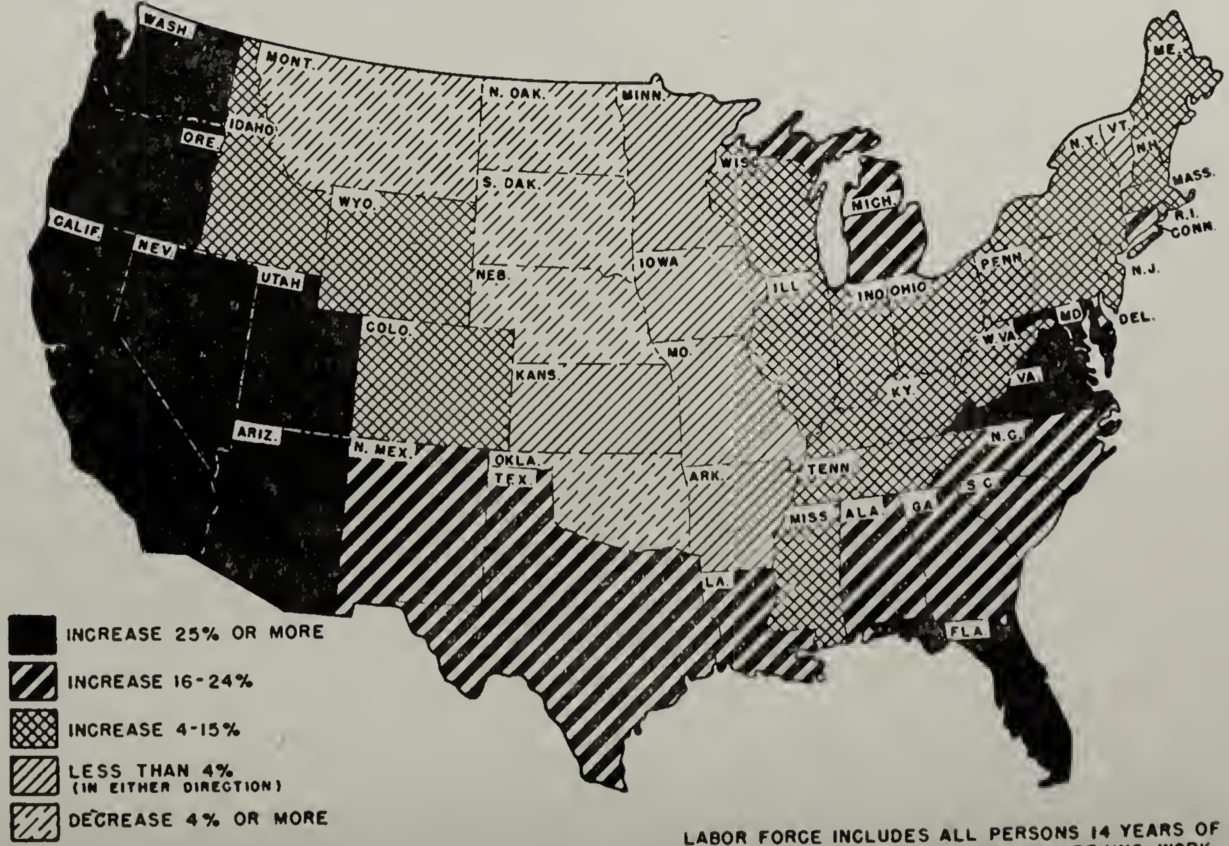
PROSPECTIVE LABOR FORCE CHANGES, BY STATE
1940 – 1950



LABOR FORCE INCLUDES ALL PERSONS 14 YEARS OF AGE AND OVER WHO ARE WORKING OR SEEKING WORK.

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

State and Regional Variations in Prospective Labor Supply

LABOR, business, and government groups engaged in labor-market analysis or concerned with problems of maintaining high levels of employment need some quantitative measure of prospective labor supply in their particular States or regions. An estimate of the total number of persons who will be working or seeking work provides a framework for the analysis of a variety of social and economic problems relating to employment, industrial location, marketing, housing, and social security. This report contains basic information on past trends and wartime developments in labor-force growth which will aid in the preparation of such an estimate for each of the 48 States.

The Pacific Coast States and the South are expected to register the largest relative gains in labor force between 1940 and 1950. (See map on opposite page and table 4, p. 20.) On the other hand the Great Plains States stretching from North Dakota to Oklahoma will probably suffer a net loss in working population. Migrants, drawn largely from the South and the Great Plains States, accounted for much of the rapid expansion of labor supply on the Pacific Coast during the war. Most of these migrants are likely to remain in their new locations because their movements followed a well-established long-term trend. The predominantly rural South, despite the fact that it loses many workers through migration to other regions, ranks second to the West Coast in the prospective rate of labor-force growth because of its relatively high birth rate. The industrial Northeast accounts for about half of the Nation's working population, but lags behind the rest of the country in prospective labor-force growth because its birth rates are relatively low and it does not characteristically draw workers from other regions.

Two types of data are presented here for use in estimating the size of each State's labor force in 1950, a year when short-run dislocations of the postwar transition period are expected to be over.

First, the base figure shown is the "normal" labor force in 1950—the work force that would have been expected if peacetime trends in labor-market participation and interstate migration had continued after 1940 and if economic conditions similar to those of 1940 had prevailed. The normal estimates, although not predictions of the actual size of the labor force in each State, provide a basis from which realistic estimates may be made.

Second, data are presented on the wartime changes in the labor force of each State. This material will aid in estimating the extent to which the actual size of the labor force in 1950 may differ from the normal level.

Normal Growth of the Labor Force, 1940 to 1950

NATIONAL CHANGES

A brief examination of normal labor-force projections for the Nation as a whole between 1940 and 1950 shows a number of broad trends in population growth and labor-market participation which operate in all States. In addition, the national trends serve as a background against which State and regional variations can be studied.

[1] Data presented in this table cover total labor force including armed forces. All data at April seasonal level. Annual average for total United States is about three-fourths of a million higher.

[2] Data from 1940 census have been revised upward for comparability with current census series. Preliminary, pending release of official revision of United States total by Bureau of the Census. See Appendix A, section 1.

[3] This projection assumes (1) continuation of prewar trends in the percentage of the population that works or seeks work; (2) economic conditions in 1950 similar to those of 1940; and (3) no interstate migration between 1940 and 1950. See Appendix A, section 2.

[4] Assumption (1) and (2) same as above, but interstate migration between 1940 and 1950 assumed to be twice the 1935–40 volume. See Appendix C, section 3.

Estimates of normal labor force for the United States have been constructed by projecting 1920 to 1940 relationships between population and labor force through the decade 1940–50.[1] The decennial increases in the labor force and population from 1920 to 1940 and the normal increase from 1940 to 1950 are shown in the following tabulation:

	Increase (in thousands)		
	1920–30	*1930–40*	*1940–50 (normal)*
Population, 14 years of age and over: Total	14, 957	12, 002	9, 205
Male	7, 134	5, 466	3, 920
Female	7, 823	6, 536	5, 285
Labor force: Total	[1] 7, 359	5, 895	6, 052
Male	[1] 5, 110	3, 276	2, 570
Female	[1] 2, 249	2, 619	3, 482

[1] Since data for 1920 are not available on a "labor force" basis, the 1920–30 change refers to "gainful workers."

---

[1] Labor-force projections for the United States as a whole appearing in this article represent preliminary revisions by the authors of estimates prepared by the Bureau of the Census and published in Population, Special Reports, Series P–44 No. 12, Bureau of the Census (Washington), June 12, 1944. The revisions are designed to be consistent with current Census estimates which are based on a revised interviewing procedure adopted in July 1945. See Bureau of the Census, Monthly Report on the Labor Force, especially MRLF No. 39, September 20, 1945.

Despite the expected decline in the rate of population growth and an assumed continuation of past trends toward longer schooling and earlier retirement, the projected increment to the labor force during this decade is somewhat larger than the increase during the 1930's.

The long-term trend toward an increasing number of women workers is the major factor supporting the large normal labor-force growth during the current decade. Over the years, it has been possible for a larger proportion of women to work outside the home because of greater mechanization of household and industrial processes, increasing urbanization, decline in the birth rate, and social attitudes more favorable to the employment of women.

On the basis of peacetime expectations, the national labor force in 1950 would number about 60.8 million persons—43.6 million men and 17.2 million women.[2]

STATE AND REGIONAL VARIATIONS

The rate of expansion of the national labor force during the decade 1940–50 represents the net effect of widely varying rates among the States. Differences in the birth rate and interstate migration play the leading roles in causing these variations.

Differential Fertility and "Natural" Labor-Force Growth

In the absence of migration, the South would be expected to have the fastest growing labor force in the Nation between 1940 and 1950. This is attributable to the high birth rates which prevail in the predominantly rural Southern States. Rural areas throughout the country have significantly higher fertility rates than urban areas. Regional differences in the "natural" rate of labor-force growth [3] are as follows:

	Natural growth in the labor force, 1940–50 (percent)
United States	11
North	8
South	18
West	6

In the broad region called the South,[4] the labor force of only two States, Delaware and Maryland (which are not typical of the other Southern States), would be expected to grow at a slower rate between 1940 and 1950 than the 11-percent natural increase anticipated for the Nation as a whole (table 1, column 3). The labor force in North Carolina, South Carolina, Georgia, and Alabama would be expected to grow more than twice as fast as the national labor force. In 24 out of 32 States in the North and West, the natural rate of labor-force growth would fall below the corresponding rate for the Nation. The lowest rates of labor-force growth in the country would prevail in the geographic division embracing the trio of Pacific Coast States—California, Oregon, and Washington.

---

[2] All data presented in this article cover total labor force including the armed forces. Projections are made at April seasonal level (the time of year when the decennial census is usually taken). On an annual average basis, the United States total labor force would be about three-fourths of a million higher.

[3] The "natural" rate of labor-force growth is here defined as the projected rate of growth, assuming no interstate migration.

[4] Regional classifications used in this article are the same as those used by the Bureau of the Census. See tables for States included in each region

In every State the natural rate of increase in the labor force is very much greater for women than for men. This reflects the increasing participation of women workers as well as the declining proportion of boys and older men in the labor force. In the absence of interstate migration, the number of male workers in the Pacific Coast States, Nevada, and the District of Columbia would be expected to decline between 1940 and 1950, but these decreases would be more than offset by gains in the number of women workers. (See Appendix B, tables 1 and 2.)

Replacement rates.—Thus far natural labor-force growth has been dealt with only in terms of *net* changes between 1940 and 1950. But these net changes result from differences between the number of persons who enter the labor market and the number who leave. The accessions to and separations from the labor force are analyzed in this section, not only to indicate their magnitude, but also to highlight State differences in the competitive position of new entrants to the labor market. The analysis is confined to male workers because the movements of women in and out of the labor market are complicated by changes in marital and family status.

Areas of relatively high birth rates and comparatively young population will have more new workers entering the labor force and fewer older workers leaving than areas where the population is relatively old. In the South, for example, some 3,895,000 young men (exclusive of in-migrants) would be expected to enter the labor force between 1940 and 1950, whereas only 2,321,000 would leave because of death or retirement.[5] (See table 2, columns 1 and 2.) This means an average of 168 accessions for every 100 separations—a *replacement rate* of 168. In other words, if there were no migration into or out of the South, every 100 men leaving that region's labor force between 1940 and 1950 would be replaced by 168 new male workers. This rate is much higher than the rates for the North (118) or the West (107). Replacement rates for individual States tend to cluster about the regional average (see chart 1), but there are some exceptions, such as New Mexico, Arizona, and Utah, where replacement rates more nearly resemble those of the South than those of the West. On the other hand, the pattern of labor-market accessions and separations in Delaware, Maryland, District of Columbia, and Florida is more like the North than like the South.

---

[5] Figures exclude accessions and separations of seasonal or intermittent workers.

The differences in the relation between labor-market accessions and separations are reflected in the composition of the labor force at any one time. If there were no interstate migration between 1940 and 1950, 28 percent of the South's male labor force in 1950 would have less than 10 years' labor-market experience as compared with 24 percent in the North and 23 percent in the West. In South Carolina, one out of every three men in the 1950 labor force would be a new worker added after 1940; in California the corresponding figure would be only one out of every five.

TABLE 2.—*"Natural" and "Normal" Accessions, Separations, and Replacement Rates for the Male Labor Force, by State, 1940 to 1950*

[1] Assumes no interstate migration between 1940 and 1950. See Appendix A, section 6.

[2] Assumes interstate migration between 1940 and 1950 to be twice the 1935–40 volume. See Appendix A, section 7.

[3] United States, regional, and divisional totals are less than the sum of their components because they exclude accessions and separations due to migration between States within the United States, region, or division.

State variations in replacement rates should not be interpreted without reference to variations in economic opportunity. A State with a rapidly expanding economy may easily absorb 200 replacements for every 100 persons leaving the labor force, whereas a less fortunate State might have difficulty providing employment opportunity for say 110 replacements. Given *equal* employment opportunity for two States, however, jobs would be harder to find in the one with the higher replacement rate because on the average more workers would be competing for each job opening. The difficulty of finding jobs would be greatly accentuated in a State with both a relatively high replacement rate and relatively low employment opportunity.

Actually, the areas with the highest replacement rates and the greatest rates of natural labor-force growth tend to be the ones where economic opportunity is below par. This disparity between labor

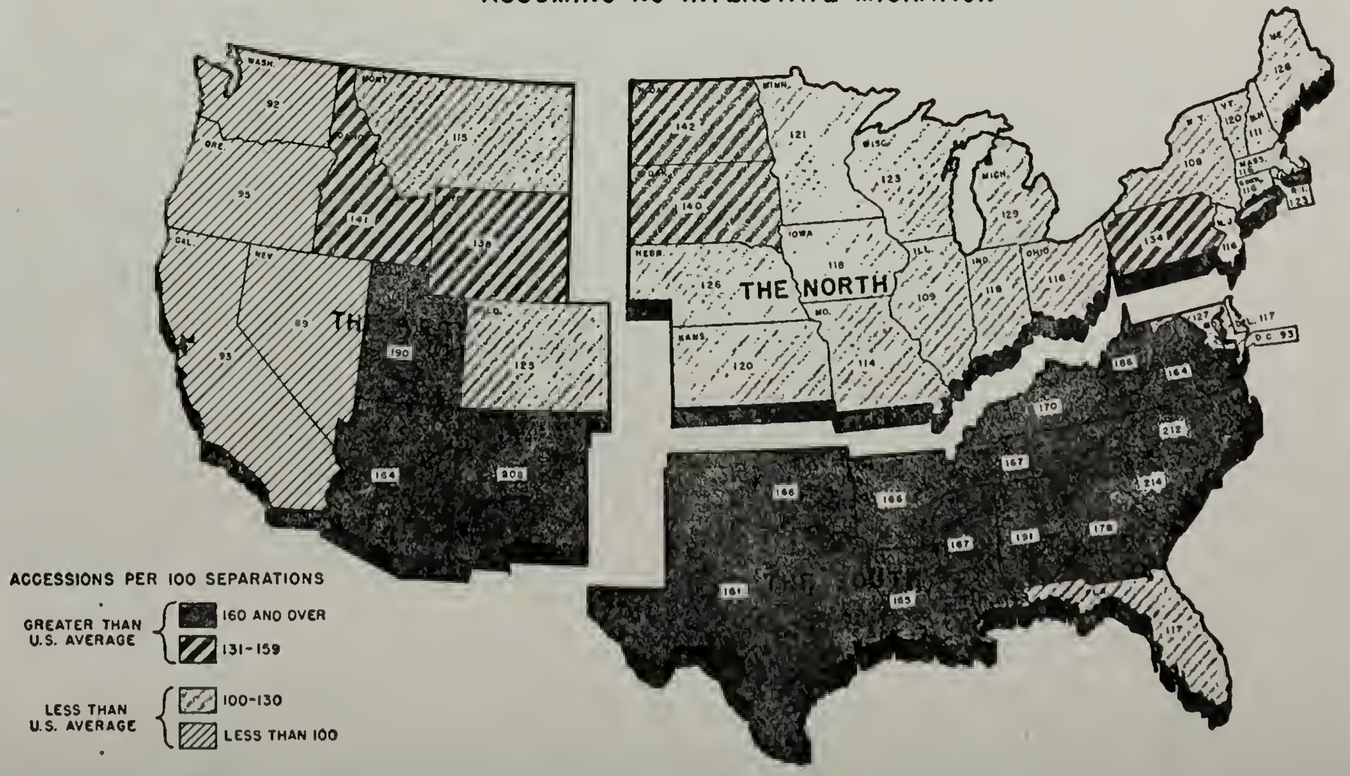
ASSUMING NO INTERSTATE MIGRATION



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

supply and economic opportunity has resulted in a consistent pattern of internal migration. The South and Great Plains characteristically have been losers in the give and take of population between regions. The West, on the other hand, has been able to draw large numbers of people from other regions of the country, while losing few. The effect of large-scale migration on State variations in labor-force growth is shown in the next section.

Internal Migration and "Normal" Labor-Force Growth

Because of the extreme importance of population movements to the supply of labor in a given State, the estimates of "normal" labor-force growth include an assumption with respect to interstate migration. For this purpose, the rate of interstate migration between 1935 and 1940 was projected through the decade 1940–50. The "normal" labor force for each State, therefore, consists of a projection of migration movements as well as trends in labor-market participation. In the procedure employed no attempt was made to estimate the *actual magnitude* of migration. But the prewar population movements do reflect a migration *pattern* that prevailed during the war and is likely to carry over into the postwar period.[6]

Since these normal labor force estimates by State assume a prewar migration pattern, there is also implicit the assumption that the prewar distribution of employment opportunity will not shift radically. In view of the past stability in the geographic distribution of economic resources and opportunity, both in years of war and peace,[7] there is a strong likelihood that this distribution will not change significantly in the next 5 years.

Estimates of normal labor-force growth and replacement rates between 1940 and 1950 by State and region including allowance for interstate migration are shown in tables 1 and 2. The introduction of the prewar migration pattern exerts great influence on the State and regional rates of labor-force growth as a comparison of these rates with those computed on a no-migration basis readily indicates (see chart 2).

---

[6] See Demographic Aspects of World War II: Migration. Paper delivered before the American Sociological Society (Cleveland, Ohio, March 1, 1946), by Henry S. Shryock, Jr., and Hope Tisdale Eldridge. It should be reemphasized at this point that the so-called normal labor-force projections assume economic conditions similar to those of 1940. Their main function is to serve as a base upon which more realistic projections can be made and not to estimate the size of the labor force under ideal economic conditions. This is especially true with regard to the migration assumption. The 1935–40 experience was chosen simply because (1) it reflected a general pattern that has prevailed in the past and is likely to continue in the future, (2) the time reference is close to the 1940 conditions to which the "normal" projections apply, and (3) there are more data available on the characteristics of migrants during the 1935–40 period than during any other period.

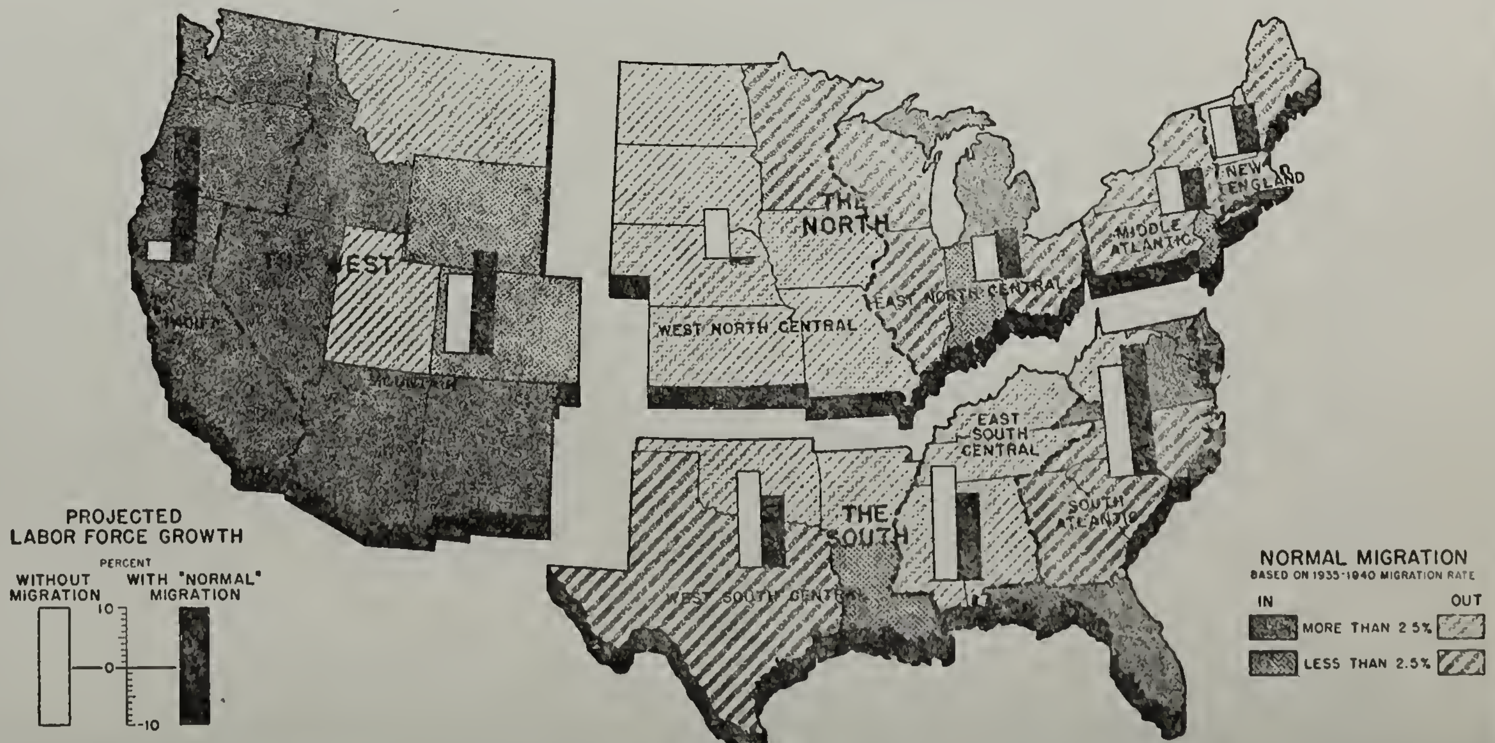
[7] On this subject see National Resources Committee, Structure of the American Economy, Philadelphia, 1939; Is Industry Decentralizing? by Daniel Creamer, Philadelphia, 1935; Growth of American Manufacturing Areas, by Glenn E. McLaughlin, Philadelphia, 1935; Regional Distortions Resulting from the War, in Survey of Current Business, October 1943.

CHART 8

EFFECT OF MIGRATION ON NORMAL LABOR FORCE GROWTH

1940–1950

SOUTH AND GREAT PLAINS, WHERE NATURAL GROWTH OF LABOR FORCE OUTSTRIPS OPPORTUNITIES FOR EMPLOYMENT, SUPPLY LABOR TO EXPANDING WEST COAST



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Although the West has the slowest rate of natural increase in working population, the great inflow of migrants causes this region to have the fastest growing labor force in the Nation. California's rate of labor-force growth increases from 4 percent to 26 percent when allowance is made for migrant workers. The South, which had the highest rate of natural labor-force growth, runs second to the West when the migration factor is taken into account.

Perhaps the most striking effect of migration on labor-force growth is shown in the Great Plains States where the labor force will actually decline between 1940 and 1950, if the exodus of workers equals or exceeds the prewar rate. And the heavy migration from this region during World War II[8] leaves little doubt that by the end of this decade there will be in fact fewer workers in the area from North Dakota to Oklahoma than there were in 1940. Wartime migration, although creating some new local problems of overcrowding and expansion of populations beyond the peacetime capacities of local economies to support them, was in general a movement from areas of low or declining opportunity to more favorably situated places.

However, there is typically not enough migration from areas of low economic opportunity to drain off the surplus labor supply. Many workers are reluctant to leave familiar surroundings and family ties. The uncertainty and fear attending migration are reinforced by its cost. This is particularly significant, for it is precisely those who should move who usually lack the means to do so. Added to these factors is the general ignorance as to where employment opportunities lie. The war stimulated migration not only because new job opportunities arose but also because they were dramatized and publicized to an unusual degree.

There has been a noteworthy trend toward the development of industry in areas of surplus labor supply. During recent decades, for example, industrialization of the South has been proceeding more rapidly than in the country as a whole. Nevertheless, it appears that the resulting shift in the distribution of employment opportunity has been relatively small. Internal migration will have to continue if all workers are to be afforded useful employment opportunities.[9]

Factors Determining Deviation of Labor Force from Normal, 1950

The 1950 labor force in a given State may differ from a normal based on projection of prewar trends for two principal reasons: (1) the proportion of the population that works or seeks work may differ from that yielded by the normal projections; and (2) the actual volume of interstate migration may deviate from the assumed volume. National labor-force growth will be affected primarily by only the first of these factors; State labor-force growth will be influenced by both factors, but principally by the second.

[1] Data presented in this table cover total labor force including armed forces.

[2] Includes members of armed forces in States from which they were inducted. Preliminary, pending release of Bureau of the Census official estimate of United States total on basis comparable with current census series. See Appendix A, section 4.

[3] Assumes interstate migration between 1940 and 1945 to be equal to the 1935–40 volume. See Appendix A, section 3.

[4] Estimate includes only migrants who would be in labor force on basis of prewar patterns of labor-market participation. Any migrants who were in the labor force in April 1945 but who would not have been workers under normal peacetime conditions are counted in column 5. See Appendix A, section 5.

[5] Revised slightly from United States total of 8.1 million published in Monthly Labor Review for November 1946.

Analysis of the differential impact of the war on the labor force of each State gives insight into the probable postwar deviation of the actual labor force from normal. The wartime expansion of the Nation's labor force to a level approximately 8 million above peacetime expectations was distributed very unevenly among the States. The extent to which these State variations in wartime excess of labor force over normal were caused by differences in degree of recruitment of new workers and by "abnormal" migration is shown in table 3. The two factors may supplement one another or offset each other. For example, the fact that California's wartime labor force exceeded normal by approximately 750,000 workers resulted from the larger than usual inflow of migrants as well as from the more complete utilization of its prewar labor supply. In contrast, out-migration of large numbers of North Carolina's working population offset the "extra" workers drawn into its labor force, so that very little increase over normal took place.

The degree to which wartime change in the labor force of a given State came about through migration rather than through more extensive utilization of the resident labor supply will play a major role in determining the future size of the State's labor force. In general, the effects of migration are likely to be more lasting than the effects of drawing extra workers into the labor force from the resident population.

EXTRA WORKERS

Some indication of the extent to which extra workers will remain in the labor market may be obtained by examining the picture for the Nation as a whole. During the war, some 8 million persons who ordinarily would have been housewives, students, retired men, or others not in search of gainful employment were drawn into the Nation's labor force.[10] These included about 4 million youths of school and college age, ½ million young women aged 20–34; 2 million women over the age of 35; and 1½ million men over 25.

Two-thirds of the wartime excess labor force caused by the premature entrance of school- and college-age youths into civilian jobs or the armed forces has already disappeared. Further reductions in the number of young workers are expected within the next few years as the prewar trend toward staying in school longer is resumed. With favorable employment opportunities, however, the teen-age labor force may be expected to continue somewhat higher than a projection of prewar trends would indicate, because a greater number of students will probably take advantage of opportunities for part-time and summer work.

About 1½ million young women aged 20–34 years quit working during the first year of peace, chiefly because their husbands returned from the armed forces or they married returning veterans. The number of young women workers is now actually below the level expected from prewar trends because of the unusually large numbers of marriages and births since 1940. Continuation of a generally high rate of economic activity would keep the number of young women workers below the level anticipated by the normal projections because young women with family responsibilities would not have to work or seek work to the same extent as in 1940.

Among men over 25 years old and women over 35, the wartime expansion in the labor force was a response to a full-employment situation as well as to the Nation's war needs. Jobs were available to those who had previously been considered virtually unemployable and others who had previously preferred retirement or homemaking were brought into the labor market by the availability of attractive work at good pay. As long as employment opportunities remain substantially better than those of 1940, the number of workers in the middle and upper age groups is likely to exceed the level indicated by a projection of prewar trends, though not to the same extent as during the war.

---

[10] For more complete discussions of the characteristics of extra wartime workers and the factors affecting their continued labor-market participation, see Sources of Wartime Labor Supply in the United States in Monthly Labor Review, August 1944; "Extra" Workers in the Postwar Labor Force, in Monthly Labor Review, November 1945; and The Labor Force in the First Year of Peace, in Monthly Labor Review, November 1946.

When the surplus of middle-aged and older workers is balanced against the deficit of young women workers, however, it is likely that the national labor force will not exceed normal by more than 1½ million, or 2 to 3 percent, in 1950. Thus, in most States, the carryover from the more complete utilization of labor supply during the war will probably be relatively small. In some States, however—especially those with a large proportion of older men and middle-aged women in the labor force—failure to take account of the extra workers remaining may result in a fairly significant understatement of the available labor supply.

INTERSTATE MIGRATION

The extent to which the rate of interstate population movement between 1940 and 1950 will differ from the 1935–40 rate assumed in the normal estimates presented here is far less predictable than the extent to which wartime extra workers will remain in the labor market. Although the *pattern* of wartime migration was very similar to that which had prevailed for some time before the war, the *volume* of 1940–45 civilian migration alone was considerably greater than that of total migration for the 5 prewar years used to compute the "normal" estimates.

The effect of this relatively heavy civilian migration in causing the labor force of each State to deviate from the assumed normal in 1945 is shown in table 3. The deviations from normal arising from migration are much more likely to persist through 1950 than are the deviations caused by the participation of extra workers during the war. Of course, there will be State variations in the extent to which gains and losses through "abnormal" migration are retained. Under certain circumstances the gains and losses may be not merely retained but increased. Whether deviations from normal because of migration are increased, retained, or decreased between 1945 and 1950 will depend on the net result of several opposing forces.

The pent-up migration plans of servicemen have been a major force exerting an upward pressure on the volume of postwar migration. The estimates of actual labor force in April 1945 (table 3) include armed forces in their State of origin, and there may have been considerable migration of ex-servicemen following demobilization. According to an Army survey in the summer of 1944, 1 out of every 10 servicemen did not intend to return to the State in which he lived before the war.[11] The survey further indicated that the migration of demobilized servicemen would be expected to follow the pattern of prewar and wartime movements of civilians.

If employment is maintained at the current high levels, migration will be further stimulated. There is typically more net interstate population movement in good times than in bad. The existence of opportunity elsewhere generally creates a stronger impetus for migration than the lack of opportunity at home. And in times of depression, the relative security of even a bare subsistence on a farm may be more attractive than the insecurity of going jobless in the city. Moreover, during depression periods there is considerable movement from cities back to farms which is against the prevailing direction of migration. This tends to hold down the net interchange of population between States. In view of the large volume of unemployment that existed during the period 1935–40, the volume of migration during that period (used as a basis for the "normal" estimates) is probably below par for more prosperous times.

On the other hand, migration between 1945 and 1950 may be slowed down by virtue of the large-scale movement during the first half of the decade. The capacity of certain areas to absorb in-migrants may be glutted, at least temporarily, by the tremendous inflows of population during the war. In addition, overexpansion of population in relation to postwar opportunities may cause some reverse migration. The occurrence of a severe depression would also retard the characteristic flow of population from farm to industrial areas.

On balance, if conditions of high employment prevail, the volume of migration between 1945 and 1950 will probably equal or exceed the volume assumed in the "normal" estimates. Even if the rate of migration were to fall below the "normal" rate, during the second half of the decade, the decline would probably not nearly offset the unusually large flow of migrants between 1940 and 1945. In either case, therefore, the volume of migration for the entire decade, 1940–50, would exceed that based on the prewar experience; allowance for this factor should be made when adjusting the "normal" labor-force estimates for 1950.

State Estimates of the Labor Force, 1950

As indicated in the introductory paragraphs of this article, the State estimates of normal labor-force growth and wartime deviations from normal will aid in evaluating the prospective labor supply in each State. The insight which this material provides, however, should be supplemented by other information that is available on the work force of the individual States.

---

[11] See Postwar Migration Plans of Army Enlisted Men, in The Annals of the American Academy of Political and Social Science, March 1945.

Table 4 presents three separate estimates of the 1950 labor force in each State, based on the data presented in tables 1 and 3, but computed on the basis of varying assumptions as to future interstate migration movements. (See p. 20.)

In order to demonstrate the manner in which the data presented in tables 1 and 3 can be used to appraise the wartime experience and postwar prospects of the labor force in individual States, two States with substantially different labor-market characteristics have been selected for more detailed analysis. Assumption B, table 4, is used for purposes of illustration, but it is not necessarily the most reasonable assumption for the particular States involved.

IOWA

In 1940, approximately 992,000 Iowans were working or seeking work. Wartime pressures brought the labor force (including armed forces personnel from the State) to a total of 1,103,000 in April 1945—an 11-percent rise. Nevertheless, by 1950, the work force is expected to number less than 970,000—actually below the 1940 level.

The wartime expansion in Iowa's working population represented the net effect of several opposing forces. The main reason for the rise n the labor force was the increased participation of housewives, students, retired persons, and others normally not working. Approximately 167,000 of these "extra" wartime workers entered in response to unusual labor demands. This number was supplemented by about 42,000 entries that would have been expected from natural population growth and continuation of prewar trends in the percentage of the population that works or seeks work. The total inflow of 209,000 nto the labor market during the war was partially offset by a net migration from the State of 98,000 civilian workers who might otherwise have participated in Iowa's war effort. The end result was an ncrease of 111,000 in the labor force between 1940 and 1945.

There is reason to believe, however, that the effect of the wartime out-migration will be more lasting than that of the wartime accessions. Many who left the State during the war are unlikely to return, unless a severe depression should strike the areas to which they moved. Iowa, being a farm State, has customarily exported labor to the expanding industrial areas. Moreover, mechanization of farm processes has made it possible to plant and harvest larger crops with fewer workers. Between 1935 and 1940, the number of persons moving out of Iowa exceeded those moving in by 61,000, and between 1940 and 1945 the State sustained a net loss of an additional 228,000 civilians (including the 98,000 workers mentioned above). These figures do not include any members of the armed forces, originally from Iowa, who may have decided to settle in other States after their discharge. Iowa is likely to continue to lose population to other States, though to a lesser extent than during the war.

Most of the extra workers drawn into the labor force from the resident population of the State are likely to drop out by 1950. In the Nation as a whole, two-thirds of 8 million extra wartime workers quit the labor force during the first year of peace. It is likely that by 1950 those remaining will make up not more than 15 to 20 percent of the wartime total.

Normally, the labor force in Iowa would be expected to grow from the 1940 level of 992,000 to a total of 1,007,000 by 1950. It seems likely, however, in view of the considerations noted above, that the work force in 1950 will be approximately 970,000.

The tabulation which follows summarizes the derivation of the statistics used in the analysis of labor-force developments in Iowa.

	Number (in thousands)	*Source*
1940 labor force	992	Table 1.
1945 labor force	1,103	Table 3.
(1) normal labor force	1,002	Table 3.
(2) deviation from normal	101	Table 3.
(a) caused by participation of "extra" workers	167	Table 3.
(b) caused by "abnormal" migration	−66	Table 3.
1950 labor force	966	1+2 (below).
(1) normal labor force	1,007	Table 1.
(2) deviation from normal	−41	a+b (below).
(a) caused by participation of "extra" workers	25	Assumed to be 15 percent of 1945 extra workers (2a above).
(b) caused by "abnormal" migration	−66	Assumed same as in 1945[1] (see 2b above).

---

[1] It is assumed that the net number of workers who move out of Iowa between 1945 and 1950 will be the same as would be expected on the basis of the 1935–40 experience.

WASHINGTON

In response to high wartime demands for labor, the working population of the State of Washington increased by 286,000 between 1940 and 1945 to a total of 1,028,000 (including armed forces personnel from the State). By 1950, the labor force is expected to number roughly 950,000, which is considerably above the 1940 level of 742,000, though short of the wartime peak.

Several factors combined to cause the wartime expansion in Washington's work force. Increased participation of housewives, students, retired persons, and others normally not working accounted for approximately 154,000 of the additional workers. In-migration of workers from other States resulted in a net gain of another 119,000.

The remaining increment of about 13,000 workers is the gain that normally would have been expected from natural population growth and continuation of prewar trends in the percentage of the population that works or seeks work.

It is likely that the great majority of the workers who moved to Washington during the war will remain in the State. Washington has typically been an importer of labor. Between 1935 and 1940, the number of persons moving into the State exceeded those moving out by 80,000. This movement was accelerated between 1940 and 1945 as the State gained an additional 273,000 civilians (including the 119,000 workers mentioned above) through in-migration. These figures do not include any members of the armed forces from other States who may have decided to settle in Washington after their discharge.

Judging from the national experience and prospects, added participation of workers normally outside the labor force will not account for more than 2 or 3 percent of the 1950 labor force in Washington.

On the basis of prewar trends, the labor force in Washington would have been expected to increase from 742,000 in 1940 to 843,000 in 1950. It seems likely, however, in view of the increase during the war that the 1950 labor force will be approximately 950,000.

The following tabulation outlines the derivation of the statistical material used in describing past and prospective labor-force changes in Washington.

	Number (in thousands)	*Source*
1940 labor force	742	Table 1.
1945 labor force	1, 028	Table 3.
(1) normal labor force	796	Table 3.
(2) deviation from normal	232	Table 3.
(a) caused by participation of "extra" workers	154	Table 3.
(b) caused by "abnormal" migration	78	Table 3.
1950 labor force	944	1+2 (below).
(1) normal labor force	843	Table 1.
(2) deviation from normal	101	a+b (below).
(a) caused by participation of "extra" workers	23	Assumed to be 15 percent of 1945 extra workers (2a above).
(b) caused by "abnormal" migration	78	Assumed same as in 1945[1] (see 2b above).

---

[1] It is assumed that the net number of workers who move into Washington between 1945 and 1950 will be the same as would be expected on the basis of the 1935–40 experience.

---

[1] Data presented in this table cover total labor force including armed forces. All data at April seasonal level. Annual average for total United States is about three-fourths of a million higher.

[2] From table 1, column (1).

[3] From table 3, column (1).

[4] All three projections assume that the 1950 labor force of each State will include some "extra" workers who would not be in the labor force on the basis of the prewar patterns of labor-market participation assumed in the "natural" and "normal" projections (table 1). Participation of "extra" workers in each State is assumed to be 15 percent of the wartime extra-worker total (table 3, column 5). All three projections take account of net civilian interstate migration between 1940 and 1945. None of the projections make allowance for migration from foreign countries between 1940 and 1950. Assumptions with respect to interstate migration between 1945 and 1950 are as follows (see Appendix A, section 8):

Assumption A. Whatever new interstate migration takes place between 1945 and 1950 will be offset by return of wartime migrants to their prewar States of residence so that interstate migration in the last half of this decade will have no net effect on the size of the labor force in each State.

Assumption B. The net number of workers who move between States during the period 1945–50 will be the same as would be expected on the basis of 1935–40 experience.

Assumption C. Net interstate migration of all workers between 1945 and 1950 will be equal to the net interstate migration of civilian workers between 1940 and 1945. Migration of workers on this scale during the second half of the decade could come about with a considerably smaller total population movement than occurred during the first half because wartime civilian migrants included large numbers of servicemen's dependents and a relatively small proportion of men of working age.

Appendix A.—Technical Notes on Estimating Procedures

The State labor-force estimates presented in this bulletin are consistent with current national totals from the Bureau of the Census Monthly Report on the Labor Force (MRLF) which are based on a revised interviewing procedure adopted in July 1945. The effects on the Census series resulting from the introduction of the new interviewing techniques are described in Bureau of the Census MRLF No. 39, September 20, 1945. National totals for April 1940 and April 1945 appearing in this bulletin are preliminary pending release of official revisions for these dates by the Bureau of the Census.

The methods used in deriving the estimates presented in tables 1 to 4 and in Appendix B, tables 1 and 2, are outlined below.

1. Labor Force, 1940. (Table 1 and Appendix B, tables 1 and 2.)

State labor force estimates for 1940 were based on the Sixteenth Census of the United States, 1940, Population, Vol. III, The Labor Force. These data by age and sex were adjusted to preliminary national labor-force figures for 1940 designed to be consistent with the revised MRLF series.

2. "Natural" Labor Force, 1950. (Table 1 and Appendix B, tables 1 and 2.)

a. 1940 State population figures by age and sex (and color for the South) were obtained from the Sixteenth Census of the United States, 1940, Population, Vol. II, Characteristics of the Population, Part 1, United States Summary, table 26; and Vol. IV, Characteristics by Age, Parts 2 to 4, table 1.

b. To obtain a 1950 population aged 14 years and over classified by age and sex (and color for the South), the 1940 population 4 years and over was aged by 10 years. Survival rates, based on Census life tables for 1939–41, were used to decrease the population by the number of deaths expected between 1940 and 1950.

c. 1940 State worker rates by age and sex (and color for the South)[1] were then applied to the corresponding 1950 population groups to obtain a 1950 labor force, unadjusted for trend.

---

[1] 1940 worker rates, i. e., the proportion of labor force to population in given groups, were obtained from the Sixteenth Census of the United States, 1940, Population, Vol. III, The Labor Force.

d. Finally, these projected labor-force figures by State were adjusted to national "normal" labor-force estimates, by age and sex, for 1950 to take account of long-term trends in worker rates. The estimates of "normal" labor force were those of the Bureau of the Census[2] adjusted to be consistent with the current Census Monthly Report on the Labor Force series.

3. "NORMAL" LABOR FORCE, 1945 AND 1950. (Tables 1 and 3 and Appendix B, tables 1 and 2.)

a. For 1950, the base population figures by age and sex (and color for the South), assuming no migration, are those obtained in section 2*b*. The corresponding population figures for 1945 were derived in a similar manner by aging the 1940 population 9 years of age and over by 5 years.

b. Shifts through migration were accounted for by using the 1935–40 volume of net interstate migration by age and sex (and color for the South) for the 1940–45 period.[3] For the 10-year period 1940 to 1950, the figures were doubled.[4] Total populations by age and sex for the years 1945 and 1950, assuming migration, were obtained by adding the volume of assumed migration 1940–45 and 1940–50 to the survived populations in 1945 and 1950, respectively. While the procedure employed does not attempt to estimate the *actual magnitude* of migration changes during the current decade, it is consistent with the migration *pattern* that prevailed during the war and is likely to carry over into the postwar period. An analysis of wartime and prewar migration patterns by Shryock and Eldridge of the Bureau of the Census shows a close similarity between the war and prewar periods.[5] The correlation coefficients between annual average net interstate migration for the period 1940–45 and the corresponding annual averages for three earlier periods for which data are available are as follows:

1940–45 correlated with—	*Coefficient*
1935–40	.92
1930–40	.79
1920–30	.81

---

[2] Bureau of the Census, Population, Special Reports, Series P-44, No. 12, Normal Growth of the Labor Force in the United States: 1940 to 1950, by John D. Durand and Loring Wood.

[3] Migration data obtained from Sixteenth Census of the United States, 1940, Population, Internal Migration, 1935 to 1940, Age of Migrants.

[4] This procedure is conceptually not the best that could be devised, inasmuch as the age composition of migrants who moved during a 5-year period would be expected to differ from that of migrants who moved during a 10-year period. Because of the approximate nature of the entire migration assumption, however, it was felt that the use of a more intricate and time-consuming method, which would have in turn involved additional assumptions as to the timing of migration over the 10-year period, would not be justified.

[5] Demographic Aspects of World War II: Migration. Paper delivered before the American Sociological Society (Cleveland, Ohio, Mar. 1, 1946).

c. The 1945 and 1950 normal labor forces, unadjusted for trend, were computed by applying 1940 State worker rates to the population estimates computed in section 2*b*.

d. The labor-force figures for each year were then adjusted to national normal labor-force totals by age and sex (see section 2*d*) for the corresponding years in order to adjust for trend.

4. ESTIMATED ACTUAL LABOR FORCE, APRIL 1945. (Table 3.)

An actual labor force for April 1945 by State was estimated by distributing preliminary estimates of the United States total (on the revised MRLF series basis) in the following manner:

a. MRLF nonagricultural wage and salary workers (except domestics).—Census State totals in 1940 were moved by the percentage change in the Bureau of Labor Statistics State estimates of nonagricultural employees for April 1940 to April 1945. The 1945 State distribution thereby derived was used to distribute the MRLF national total.

b. Nonagricultural self-employed, proprietors, domestic servants, and unpaid family workers.—The most recent distribution of this group by State is found in the 1940 census. In order to take account of subsequent changes it was assumed that the distribution would shift between 1940 and 1945 by only half as much as did the distribution of employees in nonagricultural establishments. The State distribution obtained was applied to the MRLF national figure.

c. Agricultural employment.—MRLF agricultural employment figures for family labor (self-employed plus unpaid family workers) and hired workers (wage and salary workers) in April 1945 were separately distributed by major geographic divisions. This was done by moving the 1940 census components for each geographic division by the rate of change in the corresponding Bureau of Agricultural Economics (BAE) components between 1940 and 1945 and applying the distribution obtained to April 1945 MRLF totals. Each division's family labor was, in turn, broken into State figures by the distribution of farms in 1945.[6] The two variables, when correlated from 1940 data, showed a very high relationship (.98887). Hired labor was distributed by State according to BAE State employment figures for hired labor in April 1942.

d. Unemployment.—MRLF unemployment figure for April 1945 was distributed by State according to the distribution of continued claims for unemployment compensation in April 1945.[7]

[7] Social Security Board, Bureau of Employment Security, Employment Security Activities, Vol. 1, No. 5, May 1945.

e. Armed forces.—State figures for the armed forces in April 1945 were obtained by distributing the total for that month according to the distribution of inductions and enlistments from each State for the period April 1940 to July 1945 as shown in Bureau of the Census, Population, Special Reports, Series P–46, No. 3.

f. Total actual labor-force estimates for the States were derived by summing *a* through *e*.

5. DEVIATION OF ACTUAL FROM "NORMAL" LABOR FORCE CAUSED BY ABNORMAL MIGRATION, 1945. (Table 3.)

The difference between each State's normal labor force (section 3*d*) and actual labor force (section 4*f*) for April 1945 was divided into two parts: That due to extra participation of persons who normally would not work or seek work and that due to actual migration being greater or less than the assumed "normal" migration.

a. The deviation from normal attributable to migration was derived as follows:

(1) Estimated net interstate migration of the civilian population between 1940 and 1945 was adapted from Bureau of the Census, Population, Special Reports, Series P–46, No. 3. (See Appendix B, table 3.)

(2) An over-all "normal" worker rate for civilian migrants between 1940 and 1945 was computed as follows: The 1945 "normal" age- and sex-specific worker rates were applied to the age and sex distribution of all civilian interstate migrants for the period December 1941 to March 1945 [8] to obtain an estimate of civilian migrants who would normally be in the labor force.[9] The ratio of this figure to the total number of civilian migrants for the period gave an over-all normal worker rate for migrants.

(3) This over-all normal worker rate for civilian migrants was applied to the net civilian migration estimate for each State ((1) above) to obtain an estimate of the net number of civilian migrants to or from each State, 1940–45, who would normally be in the labor force.

(4) The net number of migrant workers included in the 1945 normal labor-force estimate for each State (i. e., computed on the basis of 1935–40 migration—see section 2) was subtracted from the figure for each State derived in step (3) to obtain the deviation of actual labor force from normal caused by "abnormal" migration between 1940 and 1945.

---

[8] Bureau of the Census, Population, Special Reports, Series P–S, No. 5.

[9] Data from the 1940 Census of Population indicate that interstate migrants (1935–40) had the same worker rates age for age as nonmigrants. The worker rate for all interstate migrants 14 years of age and over exceeded that for the corresponding group of nonmigrants, but this was entirely attributable to differences in the age composition of the two groups.

b. The estimated deviation from normal due to participation of extra workers in each State was derived by subtracting the deviation due to migration from the total deviation.

6. "NATURAL" ACCESSIONS TO AND SEPARATIONS FROM THE MALE LABOR FORCE, 1940–50. (Table 2.)

The two basic sets of figures used in estimating accessions and separations were the 1940 male labor force by age and the "natural" 1950 male labor force by age for each State. (See sections 1 and 2*d.*)

a. Accessions.—All of the workers aged 14 to 23 in 1950, too young to have been counted in the labor force of 1940, were counted as accessions to the labor force between 1940 and 1950. Part of the 24- to 34-year-old labor force in 1950 was in the 1940 labor force as the 14- to 24-year-old group; the rest are new additions during the 10 years. Therefore, new labor-force entrants aged 14 to 34 in 1950 were obtained by subtracting the number of workers aged 14 to 24 in 1940 (adjusted for mortality between 1940 and 1950) from the labor force aged 14 to 34 in 1950. No allowance was made for new workers over 35 years of age in 1950, but their number is not significant.

b. Separations.—Separations from the labor force during the 10-year period are the sum of the expected deaths and retirements. They are computed in three parts:

(1) The major part of the separations occurs among workers who were 35 years and older in 1940. This is estimated as the difference between the 1950 labor force 45 years and over and the 1940 workers who were 35 years and over.

(2) For the group 14 to 24 in 1940, the estimated number of deaths is counted as total separations since there are very few retirements from the labor force among the young men in this group.

(3) There remains the group aged 25 to 34 in 1940. This is a very stable group so far as labor-market participation is concerned. Very few men enter the labor market after age 25 and very few are separated before age 44 except in case of death. Total separations were estimated by subtracting the estimated labor force aged 35 to 44 in 1950 from the labor force aged 25 to 34 in 1940. This procedure understates the number of separations by a small amount equal to the number of accessions after age 25. Thus in a few States the net separations were smaller than the expected number of deaths. In such cases the expected number of deaths were considered to be the total separations and the excess of deaths over net separations was added to accessions.

The sum of groups (1) to (3) comprises the total number of separations for each State.

c. Replacement rates.—The replacement rate is the number of accessions per 100 separations.

7. "NORMAL" ACCESSIONS TO AND SEPARATIONS FROM THE MALE LABOR FORCE, 1940–50. (Table 2.)

Accessions were considered to be composed of the 1940–50 in-migrants in a State's labor force as of 1950 plus the new entrants during the decade from the nonmigrant population; separations, the sum of the 1940–50 out-migrants who were in the State's 1940 labor force plus separations from the 1940 nonmigrant labor force during the decade.[10]

a. Migrants.—As previously indicated (section 3*b*) the number of interstate migrants in each age and sex group between 1940 and 1950 was assumed to be twice the corresponding number between 1935 and 1940.

b. In-migrant labor force, 1950.—The in-migrant male population by age for each State in 1950 was multiplied by age-specific worker rates to derive the in-migrant male labor force of each State as of 1950. These workers would be accessions to the State's labor force during the 10-year period.

c. Out-migrant labor force.—The number of 1940–50 out-migrants from each State who had been in the 1940 labor force was estimated by applying the 1940 age-specific worker rates to the out-migrant population. Since the out-migrants were distributed by their 1950 ages, worker rates for age groups 10 years younger were applied in order to estimate how many were in the 1940 labor force. For example, the 1940 worker rate for men aged 35 to 44 was applied to the group of out-migrants aged 45 to 54 as of 1950.

d. Nonmigrant labor force.—The 1940 out-migrant workers, by age (computed in 7*c* above), were subtracted from the corresponding age groups of the State's 1940 labor force to estimate the 1940 nonmigrant labor force.

e. The 1950 nonmigrant labor force was computed by subtracting from the State's projected 1950 labor force by age, assuming no migration (section 2*d*), the number of workers who would be expected to leave the State between 1940 and 1950. The estimate of total out-migrant workers was obtained by applying age-specific worker rates to the 1950 out-migrant population.

These two basic sets of figures on a nonmigrant basis were then used to obtain the accessions and separations from among nonmigrant workers. The same procedures as outlined for computing accessions to and separations from the total male labor force on the assumption of no migration were applied to these nonmigrant workers of 1940 and 1950.

---

[10] Persons who would both enter and leave a given State's labor force during the decade are not counted either as accessions or separations for that State.

8. PROJECTED LABOR FORCE, 1950. (Table 4.)

a. All three projections assume that the 1950 labor force of each State will include some "extra" workers who would not be in the labor force on the basis of the prewar patterns of labor-market participation assumed in the "natural" and "normal" projections (table 1). Participation of extra workers in each State is assumed to be 15 percent of the wartime extra-worker total (i. e., 15 percent of column (5), table 3).

b. Assumption A.—To the natural labor-force projection for 1950 (table 1, column (2)) was added (1) the allowance for extra workers (section 8*a*), and (2) the net number of civilian migrants between 1940 and 1945 who would normally be in the labor force (section 5*a* (3)).

Thus, it was assumed that migration between 1945 and 1950 would have no net effect on the size of the labor force in each State.

c. Assumption B.—To the normal labor-force projection for 1950 (table 1, column (4)) was added (1) the allowance for extra workers (section 8*a*), and (2) the deviation of labor force from normal caused by abnormal migration between 1940 and 1945 (table 3, column (4)).

Thus the labor-force changes due to abnormal wartime migration were retained and it was assumed that interstate migration of workers between 1945 and 1950 would revert to the 1935–40 volume and pattern assumed in the normal projections.

d. Assumption C.—To the labor force obtained under Assumption B was added an amount equal to the deviation of labor force from normal caused by abnormal migration between 1940 and 1945 (table 3, column (4)). Thus, it was assumed that interstate migration of workers between 1945 and 1950 would be the same as between 1940 and 1945 (i. e., would exceed normal by the same amount as the 1940–45 volume).

[1] Data presented in this table cover total labor force including armed forces. All data at April seasonal level. Annual average for total United States is about 400,000 higher.

[2] Data from 1940 census have been revised upward for comparability with current census series. Preliminary pending release of official revision of United States total by Bureau of the Census. See Appendix A, section 1.

[3] This projection assumes (1) continuation of prewar trends in the percentage of the population that works or seeks work; (2) economic conditions in 1950 similar to those of 1940; (3) no interstate migration between 1940 and 1950. See Appendix A, section 2.

[4] Assumptions (1) and (2) same as above; (3) interstate migration between 1940 and 1950 assumed to be twice the 1935–40 volume. See Appendix A, section 3.

Summary	1
Operations in 1944 and 1945	1
Trend in formation of associations in 1945	6
State legislation	6

Bulletin No. 894 of the
United States Bureau of Labor Statistics

[Reprinted from the Monthly Labor Review, December 1946, with additional data.]

Activities of Credit Unions in 1945

THE slight upward trend in business done by credit unions in the United States in 1944, after a serious decline during the war years, was continued in 1945, although the total of loans made was still more than 40 percent below the peak of 1941. This increase took place in spite of a slight reduction in number of loans made, indicating a rise in the average size of loan. Share capital and assets which (notwithstanding the otherwise adverse business experience of the credit unions during the war) have continued to rise steadily, maintained their upward pace in 1945, showing increases of 8.1 and 9.2 percent, respectively. Reserves fell somewhat, however, both in amount and in relation to loans outstanding, declining as regards the latter from 20.7 percent in 1944 to 19.4 percent in 1945.

Both net earnings and dividends paid on share capital increased as compared with 1944. For 1945, credit union members received nearly $5,900,000 in dividends on their shares.

Because 398 credit unions went out of existence (some of them undoubtedly in war plants now closed) and only 239 were newly chartered, the total number of associations fell from 9,041 at the end of 1944 to 8,882 at the end of 1945. Partly as a result of this, the total membership declined 3.3 percent.

The State-chartered credit unions fared better during the year than the Federal associations.[1] Their membership declined 0.5 percent, as against 6.7 percent for the Federal associations; they increased their business by 0.8 percent, whereas the loans made by the Federal credit unions fell 0.1 percent. The increases in assets of the two groups of associations were 11.0 and 6.1 percent, respectively.

Operations in 1944 and 1945

Data on membership and business of credit unions in 1944 and 1945 are given in table 1.

---

[1] For the State-chartered associations the statistical data on which the present report is based were in most cases furnished to the Bureau of Labor Statistics by the State official—usually the Superintendent of Banks—charged with supervision of these associations. Reports were received from all States except Iowa. For that State and for certain items concerning which some States do not require the associations to report, estimates were made, based on the trend in other States and on the trend of the other items in the same State. All of the information for the Federal credit unions was supplied by the Credit Union Division of the Federal Deposit Insurance Corporation.

TABLE 1.—*Operations of credit unions in 1944 and 1945, by States*

[Some revisions in 1944 figures, on basis of later reports]

State, and type of charter	Year	Number of associations[1]		Number of members	Number of loans made during year	Amount of loans—

	1944	19	18	2, 582	947	168, 766	86, 660

[1] Most of the difference between the total number of associations and the number reporting is accounted for by associations chartered but not in operation by the end of the year and associations in liquidation which had not relinquished their charters.

[2] Revised.

[3] Partly estimated.

[4] Federal associations only; no State-chartered associations in this State.

[5] Federal associations only; although State permissive legislation was passed in 1945 no associations had yet been formed under it.

Fifteen States (Alabama, Arkansas, Colorado, Delaware, Florida, Idaho, Illinois, Louisiana, Maine, Montana, Nevada, North Carolina, North Dakota, Rhode Island, and Vermont) showed a membership increase. Their slight gains, however, were not sufficient to overcome the losses in members in the other States.

The prewar level of business was reached or exceeded in 1945 by both State and Federal associations in Alabama, Montana, and Vermont, by the State-chartered associations in Rhode Island, and by the Federal credit unions in Utah.

Data on the financial status of credit unions, by States, is given in table 2.

TABLE 2.—*Assets and earnings of credit unions, 1944 and 1945, by States*

State, and type of charter	Year	Number of associations [1]		Paid-in share capital	Reserves (guaranty fund, general reserve, etc.)	Total assets	Net earnings	Dividends on shares

---

[1] Most of the difference between the total number of associations and the number reporting is accounted for by associations chartered but not in operation by the end of the year and associations in process of liquidation which had not relinquished their charters.

[2] Partly estimated.

[3] Federal associations only; no State-chartered associations in this State.

[4] Includes interest paid on deposits by State-chartered associations.

[5] Loss.

[6] Federal associations only; although State permissive legislation was passed in 1945, no associations had yet been formed under it.

Trend in Formation of Associations in 1945

Table 3 shows, by States, the number of associations formed and dissolved in 1945, and the total and number reporting at the end of the year.

TABLE 3.—*Trend of formation and dissolution of credit unions in 1945*

[1] Some revisions, on basis of later information.
[2] Partly estimated.

State Legislation

California.—Several measures were enacted affecting the credit unions. Chapter 1262 eliminated the requirement that the number of persons in the field of membership be specified when a credit union is organized, and limited votes to one per member in all associations organized on or after September 15, 1945. Chapter 651 raised the maximum amount permissible for a secured loan to $3,000 or 10 percent of the credit union's capital, whichever is greater (but in no case to exceed $10,000); and provided that on loans over $3,000 the excess must be secured by real and/or personal property. No loans may be made to directors or committee members in excess of their investment; henceforth a borrower may be elected as director or committee member, but will forfeit his office in case of default on repayment of his loan. Under chapter 438, formal meetings of the credit committee are apparently no longer required, the former provision being amended to require only that loans be approved in writing by a majority of the committee.

The duties of the supervisory committee now include the mandatory requirement that the committee make an annual audit of the books and records (ch. 1262).

A range of examination charges is established, varying according to assets of the credit union (ch. 1318), the Commissioner of Corporations being authorized to make certain adjustments in these, to suspend or revoke the licenses of associations failing to pay such charges before the end of the year, and to make extra charges for special services rendered by his office. Chapter 475 gives him certain powers over credit unions operating on an unsound basis or with impaired capital; provides that if three-fourths of the directors vote to recommend the dissolution of an association, liquidation may be carried out on vote of a majority of members; and specifies procedures for liquidation. It likewise provides for mergers of credit unions with "like community interests," upon majority affirmative vote of the directors and a three-fourths vote of the members.

Annual reports must be made to the commissioner within 90 days of the close of the calendar year, failing which an association may have its charter suspended (ch. 437). Chapter 467 permits any credit union to take out group life insurance for its members.

Colorado.—An amendment (ch. 113) permits members of the immediate family of a credit-union member to join the association and to have joint accounts with him; permits members withdrawing from the field of membership to leave in their shares and deposits, if so provided by the bylaws, but they are prohibited thereafter from borrowing from the credit union amounts in excess of their holdings; requires that 20 percent of annual earnings shall be set aside in the reserve fund until the latter equals 15 percent of loans outstanding, and thereafter 15 percent until the reserve equals 20 percent of outstanding loans; authorizes the directors (instead of membership meeting) to declare dividends; and authorizes the formation of a central credit union.

Connecticut.—This State passed a credit-union law in 1939, but no association was ever formed under it. The 1945 legislature made several liberalizing amendments to the act. By chapter 192b the previous license fee of $50 was reduced to $20 and the filing fee was set at $10. Associations formed under the act may use either the name "credit union" or "mutual benefit association," but must specify "in detail" in their articles of incorporation the proposed field of membership. Shares may be $5 or a multiple thereof. Copies of the bylaws must be supplied to members on request. The amendment permits credit associations to take out insurance on the lives of borrowers (to safeguard their loans) and to invest in bonds legal for savings banks and (not to exceed 10 percent of assets) in building and loan associations in the State. Annual meetings may vote to pay the officers compensation for their services. A new provision prohibits proxy voting at meetings.

The limit on unsecured loans was raised from $100 to $300 and on the individual member's shareholdings from $1,000 to $3,000 (but no more than $1,000 of this to be added in any calendar year).

Officers other than president, vice president, treasurer, and secretary may be provided for in the bylaws, and the manner of their election (whether by members or directors) may also be specified. The directors must meet at least once a month. A fidelity bond must be provided by the treasurer before entering upon his duties.

Florida.—Act No. 499 (ch. 23013) reduced the voting requirement for dissolution of an association from four-fifths of the members to a majority.

Indiana.—The 1945 amendment (ch. 198) reduces the total reserves required from 20 to 10 percent of the paid-in capital (after this amount is reached no further set-asides are required), permits credit unions to carry an undivided profits account, sets January 31 and July 31 as the dates for reports to the State Department of Financial Institutions, and provides that credit unions shall be subject to the same taxes as savings banks.

Maryland.—Chapter 409 authorizes credit unions to make first-mortgage loans up to $1,500 (but not exceeding 50 percent of the appraised value of the property), at a rate of interest not over 6 percent, amortized over a period not greater than 20 years; all such loans must have the approval of the Bank Commissioner. The proportion of annual earnings to be set aside in reserves was reduced from 25 to 20 percent (ch. 665); after the reserves are equal to 20 percent of the paid-in share capital, only such sums shall be required to be set aside as are necessary to keep the reserve fund at that level.

Credit unions may hereafter borrow from any source (including other credit unions) amounts not exceeding 25 percent of their assets for not longer than 90 days, but this may be extended for a like period on approval of the commissioner. A credit union may also make loans to another credit union (ch. 315). It may also, upon approval, invest its surplus capital in insured building and loan associations (ch. 666). Chapter 515 imposes a $10 franchise fee.

Massachusetts.—Chapter 37 authorizes savings banks, cooperative banks (building and loan associations), trust companies, and credit unions holding a first mortgage on real estate to take, in substitution therefore from a bona fide purchaser, a first mortgage in an amount not exceeding that due on the existing first mortgage and accumulated interest, taxes, municipal liens, and other proper charges due thereon. The same organizations are authorized (1) by chapter 46 for a period of 5 years after the termination of the war to make loans to veterans, and all limitations on the loans of such organizations are suspended as regards veterans' loans, and (2) by chapter 66 to make housing loans. Chapter 81 authorizes and prescribes conditions for trustee accounts in credit unions.

Chapter 82 amends chapter 102 of 1941 to provide that credit unions with assets of not more than $75,000 may invest not over 50 percent and those with assets of over that amount 70 percent of their shares, deposits, and guaranty fund in real-estate mortgages; however, the total liability of any member upon loans so secured shall not exceed 5 percent of the credit union assets nor $8,000. The terms upon which such loans may be made are also prescribed.

Minnesota.—By the terms of chapter 540, credit unions in Minnesota, chartered by either the State or the Federal Government, are permitted to become members of other credit unions. Annual reports are required to be filed with the Commissioner of Banks on or before January 15 of each year. The aggregate amount of borrowings of any credit union may not exceed 35 percent of its unimpaired assets. In the case of a loan to a director or committee member which exceeds the amount of his investment in the credit union, the loan must be approved by a joint meeting of the board and both committees.

Nebraska.—Extensive revisions of the credit-union law by chapter 41 require a member to own a fully paid share in order to be eligible for a loan or to vote at meetings, remove the previous limit on the maximum loan to any member and authorize the board of directors to fix the limit, permit loans to directors and committee members in excess of their holdings if approved by the credit committee and a majority of the supervisory committee in the absence of the borrower concerned, authorize the credit committee to require a borrower to pledge his shares as security, and permit the application of the shares of a defaulting borrower or withdrawing member toward payment of his loan. The directors are authorized to determine (instead of recommend, as previously) the rate of dividend on shares; this may be done on the basis of the share and loan balances as of December 15, instead of the end of the association's fiscal year, if the board chooses. It may also fix the treasurer's compensation (previously done by membership meeting). The payment of patronage refunds to borrowers is hereafter permitted, as is also the verification of passbooks by mailed notice to the member, confirmed by the member himself.

New Mexico.—A new credit-union law (ch. 129) was enacted in this State. It places the credit unions under the supervision of the State Bank Examiner, provides a filing fee of $5 for articles of incorporation and bylaws, and reserves the name "credit union" to associations formed under the act. Such an association is authorized to accept savings either as shares or as deposits, to make loans to members (who may be other credit unions as well as individual persons), to invest in any investment legal for savings or trust funds and not over 25 percent of its capital in paid-up shares of building and loan associations and in other credit unions, to borrow money aggregating not over 25 percent of its assets, and to become a member of a central credit union.

Individual membership in any credit union is limited to persons with a common bond or occupation or association or to groups within a well-defined neighborhood, community or rural district, and the members of their immediate family (but special limitations on the rights and privileges may be imposed on this latter group). Organizations of substantially the same group as the credit union membership may also be admitted, as well as other credit unions and their officers and committee members. Members leaving the sphere of operation of the association may leave in their shares and deposits if permitted by the bylaws, but may not thereafter borrow from it in amounts exceeding these holdings. Joint accounts are permitted.

The fiscal year shall end December 31 and the annual meeting must be held within the next 45 days. Special meetings may be called and held as specified in the bylaws. At all meetings each member shall have only one vote; proxy voting is prohibited except that member associations may cast their vote through a delegate.

The board of directors (not less than 5 members), the credit committee (not less than 3), and the supervisory committee (3) are to be elected at the annual meeting for such terms as the bylaws provide.

Officers—president, vice president, treasurer, and clerk (secretary)—are to be elected by the directors from their own number. The board is authorized to act upon membership applications, fix bonds for all persons handling money, determine rates of interest on loans and deposits, declare dividends, fill vacancies in the board and credit committee, set maximum shares and loans allowed per member, and have charge of all investments other than loans.

The treasurer is designated as the general manager of the association. This office may be combined with that of the clerk. No director or committee member shall be compensated as such.

The credit committee has supervision of all loans and it is to prepare the application form for loans, which must set forth the purpose for which the loan is desired, the security (if any) offered, and any other information required by the committee. For the granting of a loan, the unanimous approval of the committee members present (who must constitute a majority of the total committee) is required. Assignment of shares or deposits or the endorsement of a comaker may be regarded as security.

The supervisory committee is required to examine the books at least quarterly, as well as annually, and submit a report to the annual meeting and to such other meetings as it may regard as necessary. By unanimous vote it may suspend any director, officer, or committee member and call a membership meeting to take such action upon the suspension as the meeting may see fit.

Loans may be made only for provident or productive purposes. No director, officer, or committee member may borrow in excess of his investment in the credit union nor act as endorser for any borrower. Interest on loans is set at not over 1 percent per month on unpaid balances. No credit union may lend an amount exceeding 10 percent of its assets to another credit union.

At the end of the fiscal year, 20 percent of net earnings, plus all entrance fees (25 cents each) and fines, are required to be set aside in a reserve fund until such fund equals 10 percent of the total outstanding loans. Thereafter, only such amounts shall be set aside as are required to keep the fund at the 10-percent level. The reserve is to be used as a reserve against bad debts and losses. It may not be distributed except in case of liquidation of the association. From the net earnings remaining after appropriation for reserve the directors may declare a dividend, not to exceed 6 percent, on all shares outstanding at the end of the year, with proportional payments on shares which became paid up during the year.

A member may withdraw from membership at any time, but notice may be required. A member may be expelled by two-thirds vote of a special meeting of members. Upon withdrawal or expulsion, the holdings of such persons plus any dividend or interest due, minus any amounts owed to the association, shall be paid as funds become available. For withdrawal of funds, notice of 60 days in case of shares and of 30 days in case of deposits may be required.

Procedure for voluntary dissolution is specified, but requires that dissolution can take place only upon a four-fifths vote of the entire membership at a special meeting the purpose of which is set forth in the notice of the meeting.

Credit unions formed under the act are exempt (as institutions for savings) from all taxation except on property owned and from any stock-transfer tax.

Associations are required to file annual reports with the State Bank Examiner on or before January 20 of each year, upon penalty of fine of $5 for each day of delinquency. Their accounts are subject to audit by him (except that for associations with assets of less than $25,000 he may accept the audit of a certified accountant), at fees ranging from $25 upward.

New York.—Chapter 145 codifies previous enactments, with a considerable number of amendments. These amendments place a maximum of 15 upon the number of directors, permit the election of more than one vice president, and prohibit a member of the supervisory committee from also serving as a member of the board of directors. New members of a credit union which has been in existence for more than a year may not vote until they have been shareholders for at least 90 days. Credit unions may no longer accept deposits. Dividends from the previous year's earnings may be declared by the board during the first 3 months of the year, but the directors are held jointly and severally liable for any amount of dividend voted which exceeds the amount available for dividend. Changes in loan procedure require endorsed notes when a mortgage on real estate is taken, prevent the withdrawal of any shares pledged as security for loans (except those in excess of the amount of loan) unless approved by a majority of the credit committee, prohibit loans to another credit union in excess of 15 percent of the capital of either association, and limit the association's total investment in shares of other credit unions to 25 percent of its capital. Credit unions, however, may not hereafter invest in obligations of certain school districts or railroads, nor (except associations with assets of more than $3,000,000) in bonds of public utilities.

The term "surplus account" is to be used hereafter instead of "guaranty fund." Amounts in this account which exceed 20 percent of total liabilities may be transferred to undivided profits upon approval by the Superintendent of Banks. Associations are given permission to act as agents in selling money orders and travel checks.

North Dakota.—Chapter 143 creates a State Credit Union Board, consisting of the Bank Examiner and two members with at least 3 years' experience, chosen by the Governor from a list of 5 persons submitted by the State Credit Union League.

South Carolina.—Act No. 134 exempts from annual license fees all credit unions of State or Federal employees and building and loan associations doing a "strictly mutual business."

Texas.—Chapter 282 of the Acts of 1945 modifies the previous limitation (15 percent of capital and surplus) on borrowings of credit unions by providing that such associations may borrow up to 50 percent of their combined capital and surplus if such loans are secured by Government securities owned by the association. The 2-year limitation on credit-union loans was removed as regards those made under the Servicemen's Readjustment Act of 1944. The annual required set-aside for the guaranty fund was reduced from 20 to 10 percent of net income. The annual meeting may increase this proportion on recommendation of the directors or may decrease it whenever the fund equals or exceeds 10 percent of paid-in share capital Dividends on shares are limited to 6 percent.

Utah.—Chapter 15 codifies, under the title "cooperative banks fo personal credits," the previous enactments which had consisted o scattered provisions in the corporation, banking, and small-loan law of the State. Only a few minor changes were obtained, but it was the opinion of a Utah Credit Union League official that desirable amendments would be facilitated in the future by having all the credit union provisions in one chapter.

Wisconsin.—By chapter 58 the annual set-aside for the guaranty fund was changed from 20 percent of net income to 15 percent of gross income and the previous limitation on expenses (50 percent of income) was removed; the name of the auditing committee was changed to "examining committee" and its required examinations reduced from once every 2 months to twice a year. Articles of incorporation may be amended, at a meeting called for the purpose, by a two-thirds vote of those present (instead of two-thirds of all members). Voluntary dissolution is permitted upon unanimous vote of directors and two-thirds membership vote by ballot (previously, approval by two-thirds of entire membership present at meeting), provided not more than 10 members object.

Yearly examinations are required to be made by the State Banking Commission. The examination fees charged by the commission, which had previously ranged from $5 to $50 or more were lowered to 25 cents per $100 of assets or the actual hourly cost of examination, whichever is less.

New provisions added by chapter 58 require detailed annual reports to the Banking Commission by February 1, on penalty of fine of $1 to $10 per day of default; authorize the commission to prescribe bookkeeping and accounting methods, which must be followed by the credit unions on pain of fine not to exceed $10 per day; empower the commission to take over (subject to appeal) for liquidation any credit union violating the law, having its capital impaired, or operating in an unsound manner, and to prescribe the procedure in such cases; and specify procedures for the consolidation or merger of credit unions.

Other enactments regulate the manner of termination of bonds of officers or employees of credit unions (ch. 228) and permit the destruction of obsolete records, upon written consent of the Banking Commission (ch. 315).

LETTER OF TRANSMITTAL

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., March 27, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on the employment outlook in machine shop occupations. This is one of a series of occupational studies prepared in the Bureau's Occupational Outlook Division for use in vocational counseling of veterans, young people in schools, and others considering the choice of an occupation. The present study was prepared by Richard H. Lewis and Calman R. Winegarden with the assistance of Abraham Ringel. The Bureau wishes to acknowledge the cooperation received from other Government agencies and from unions, trade associations, trade periodicals, and companies in the machine shop field.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

EMPLOYMENT OUTLOOK IN MACHINE SHOP OCCUPATIONS

Introduction

Machine shop work represents an important ield to a young person interested in the choice of n occupation. Because of the size of the field—vell over a million workers were employed at the vartime peak in 1943—opportunities arise for nany men to enter each year. Machine shop jobs re the largest single group of skilled jobs in man-facturing, and therefore offer many workers the hance to earn better-than-average wages. Furhermore, machine shops are widespread throughut the country, and are found in many different ndustries, so that openings occur in every State.

The machine shop worker is a key figure in this ge of metal. His work is essential in the manuacture of automobiles, railway cars, airplanes, arm machinery, and a thousand other products. n addition, he makes and repairs machinery used o manufacture these products, and even the mahine tools which make all other machines. It is asy to see the critical importance of machine shop orkers in our economy.

Machining is one of the five principal methods f shaping metal; the others are casting, forging, olling, and stamping. Casting, one of the oldest nethods, consists of pouring molten metal into a nold and letting it harden into the shape of the nold. Forging, once done by the old-time blackmith with his hammer and anvil but now more ommonly done by a forging machine, involves eating the metal to soften it and then pounding into shape. Metal is made into sheets or bars y rolling or squeezing it between large rolls, as done in a steel rolling mill. Sheet metal can be further formed by stamping it with a die shaped like the final products.

Machining differs from these other methods in that it involves cutting, shaving, or grinding a piece of metal down to the desired shape, or drilling holes in it. To machine hard metals is not easy; and the process is an expensive one, because it takes so much time. But the advantage of machining is that it can be very precise; and where each thousandth of an inch counts, machining is the method most commonly used. In the manufacture of many metal products, machining begins where casting, forging, or rolling leaves off: the piece of metal is first shaped roughly by one of these methods, and then finished to precise measurements by machining. Metal objects which must fit together exactly, as in the moving parts of an engine, must usually be machined.

The place of machining among metalworking processes is shown by the way an automobile is made. The body and fenders are *stamped* out of *rolled* sheet metal. The engine, chassis, and transmission system have many parts which are first *cast*, such as the cylinder block, or *forged*, such as the axles, and then finished off by *machining*. Many other parts of the engine and frame are machined from rolled steel. Finally, the rolling mill which makes the steel sheets and bars, the drop-hammer which forges the axle blanks, the dies which stamp the fenders and body, the molding machine used in the foundry where cylinder blocks are cast—all of these contain parts which have been machined.

Machine Shops and Machine Shop Work

Nature of Machine Shop Work

Machining is done by machine tools, and a machine shop is simply a workplace in which machine tools are used. A machine tool is a power-driven machine which firmly holds both the piece of metal to be shaped and a cutting instrument, or "tool," and brings them together so that the metal is cut, shaved, ground, or drilled. In some, the tool is moved and the metal held stationary; in others, the metal is moved against a stationary tool.

The most common kinds of machine tools include the engine lathe, turret lathe, grinding machine, boring mill, drilling machine, milling machine, screw machine, shaper, and planer. The operation of lathes is known as "turning." The piece of metal being cut is rotated against the cutting tool held in the machine. Boring mills and drilling machines are among the machines that make holes in metal. Grinding machines remove metal with a power-driven abrasive wheel. Milling machines shape metal with a saw-toothed cutting tool. Planers and shapers are used to plane flat surfaces. A screw machine is a type of lathe.

Some machine shops manufacture metal products and others do maintenance work—making or repairing metal parts for equipment in use. The manufacturing shops are of two main types—job shops and production shops—depending upon the way their production is organized.

In job shops, the earliest developed, a wide variety of products may be made, with relatively few of each kind. Some job shops produce parts to order for a number of different manufacturers

General view of a small job machine shop. Before the war this plant made dairy and milk plant equipment. In this wartime scene, the shop is turning out submarine valves and aircraft parts.

NATIONAL ARCHIVES PHOTO

or use in their products. In other cases, the job hop is a department of a plant making finished roducts, such as certain types of machinery, hich either are custom-made or of which a wide ange of models must be produced to meet the pecial needs of the users. For example, a comany manufacturing pumping equipment may ave an order from a city for six specially designed umps in connection with a sewage disposal roject. The machining needed in the making of hese pumps would be done in a job shop.

Production shops, on the other hand, make large uantities of identical parts. Very commonly heir output goes into products such as automobiles r household appliances, of which large numbers f units of the same model are sold. In this way, he machine shop of an automobile parts manufacurer may be called upon to turn out thousands pon thousands of gears of the same design, or a ompany making radios will have its machine shop roduce a great many of a particular radio part. production shop, like a job shop, may be an inependent concern which sells to other companies r may be a department of a plant manufacturing etal products.

There is also an intermediate type of shop, in hich the quantities of identical parts made are reater than in job shops and smaller than in rictly production shops. Many plants manufacuring machine tools have shops of this kind.

Maintenance shops make or repair parts for etal equipment and are usually operated in conection with the business that uses the equipment. hus, a large textile mill or a cigarette factory is kely to have a machine shop which makes relacement parts for the machinery in the plant. ost maintenance shops are departments of manfacturing firms; but they are also found in every ind of business that uses metal equipment, as, r example, in railroad repair shops, electric ower plants, and large office buildings.

Whether a shop is a job, production, or mainteance shop has a lot to do with the way its work carried on and the duties of its employees. Beuse of the variety of the work in job shops, most the machine tool operators must know how to do number of different types of work. They must ow the working properties of different metals d how to adjust the machine tools to make parts many different shapes and sizes. Moreover, b shops are usually small, and this, together with the frequently changing nature of the work, means that their workers are often called upon to shift from one type of machine to another. In some cases an individual worker may carry through to completion all the machining operations on one part. For these reasons, the job shop must employ a number of men who are all-round workers—able to operate all the standard types of machine tools, and having a broad knowledge of machine-shop practices. Maintenance shops are similiar to job shops in their operation and may employ an even higher proportion of all-round workers.

Production shops, because of the large quantities of identical parts produced, are able to use many workers who can do only simple, repetitive operations on one machine. The work is planned in such a way as to limit the skill and responsibility required of the operator.

Many production shops employ skilled specialized workers to set up the machine tools (adjust the controls and set the cutting tools in place for proper machining of a desired object), which is the most complicated part of the job. When a job has been set up for him, the operator merely has to place the rough metal bars or castings into the machine, watch its operation, and check the dimensions of the work. Very often production shops use a number of "special purpose machines," which are designed to perform only one certain operation and therefore do not need special adjustments. These machines are highly automatic and the operators need little skill. As a result of the simplified methods possible in production shops, the proportion of skilled workers with wide experience is much smaller than in job and maintenance shops, where versatility and individual skills are important.

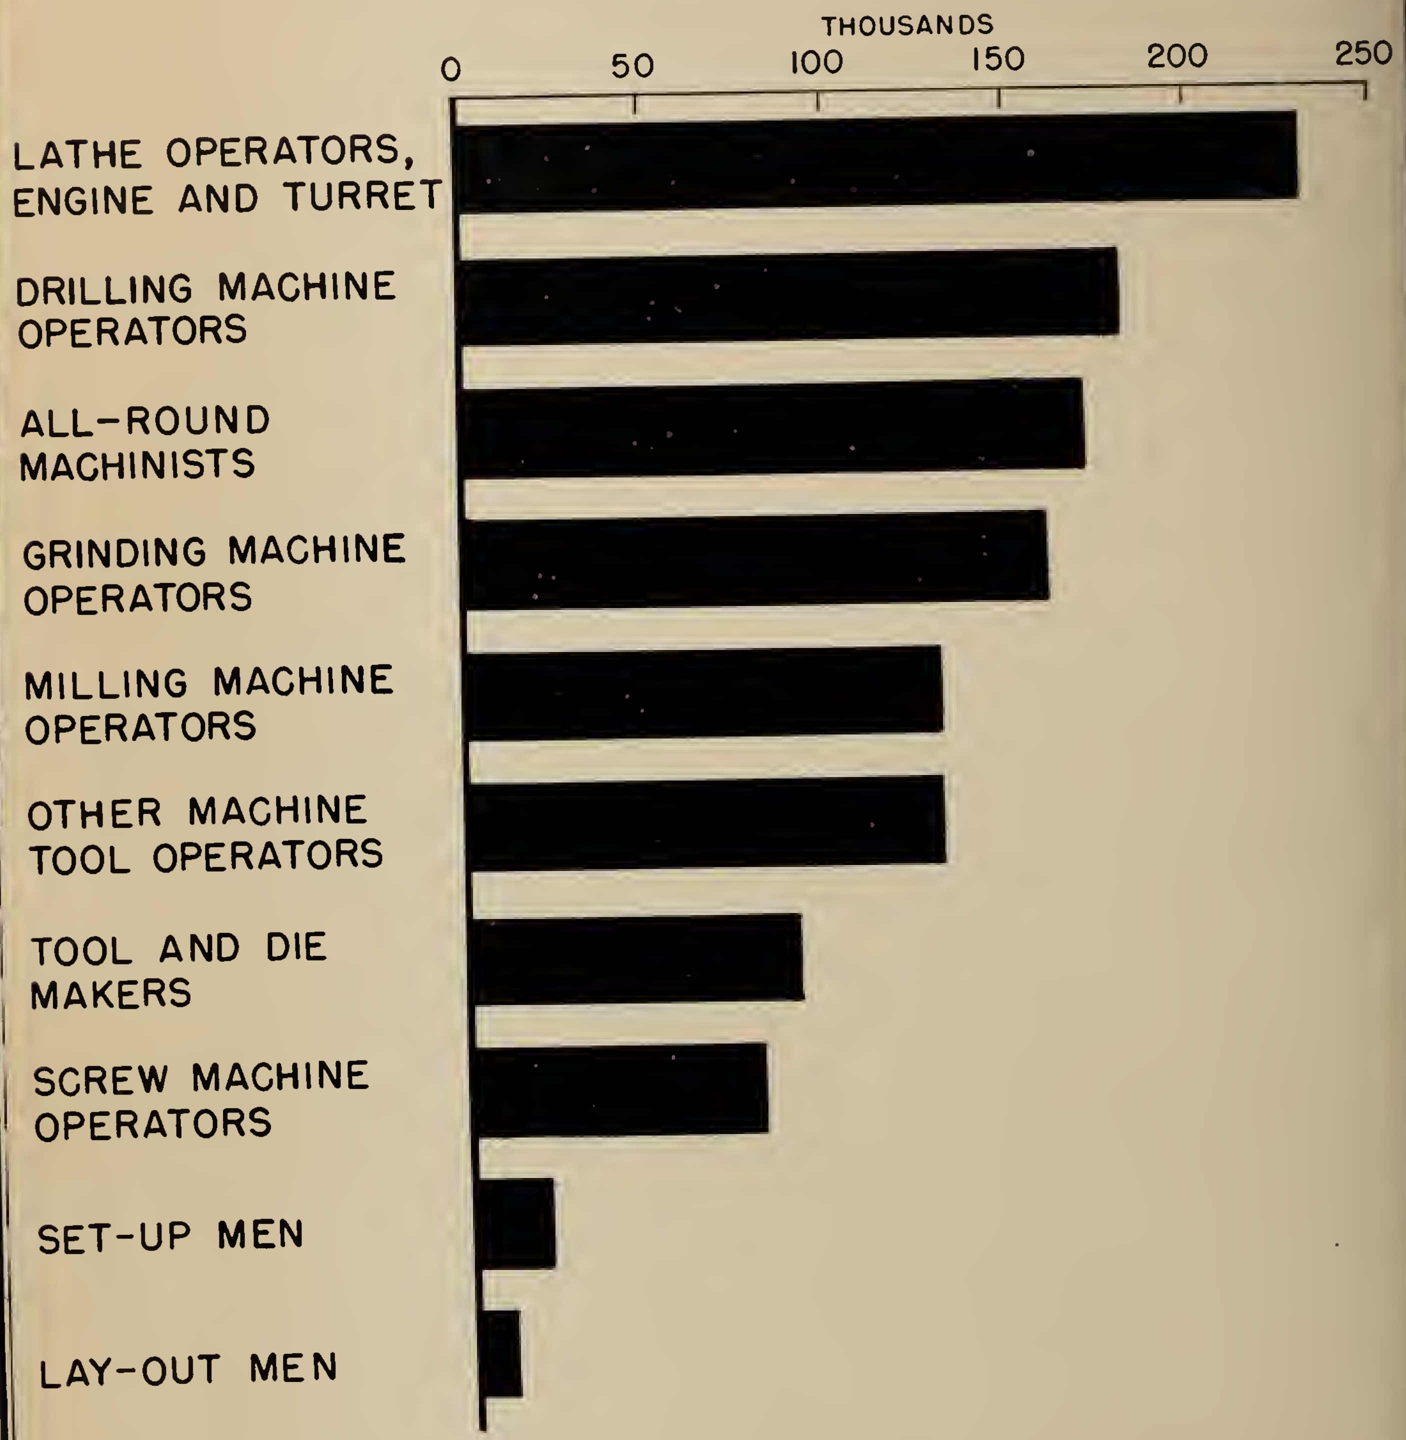
Number and Kinds of Machine Shop Jobs

Machine shop workers are the largest occupational group in metalworking and one of the most important groups in all industry. At the peak of war employment, in December 1943, about 1,200,000 workers were employed in the skilled and semiskilled machining occupations. In addition, there are many thousands of other workers, such as inspectors, helpers, and laborers, who are also employed in machine shops. Estimated employment as of December 1943 for the occupations most directly involved in machining operations is shown in chart 1.

CHART I

EMPLOYMENT IN MACHINE SHOP OCCUPATIONS

DECEMBER 1943



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Of these workers, tool and die makers are the ost skilled. Tool makers build the cutting tools hich are used in machine tools, the jigs and fix-ures which hold the work while machining opera-ons are performed, gages for measuring the work, nd various special attachments. Die makers uild the dies used in forging, stamping, die cast-g, and plastics molding.

The basic machine shop job is that of the all-und machinist. Machinists are employed mainly here workers are needed who are qualified to per-rm any of the operations in a machine shop ther than to work on only one type of machine. hus, jobs for machinists are found mainly in bbing and maintenance shops, relatively few eing found in production shops.

The specialized operators of machine tools make p the bulk of the workers in machine shops. hese workers may be either relatively skilled men ho can handle a variety of work on one type of achine, including the making of adjustments on e machine, or they may be less-skilled operators hose duties are confined principally to placing the orkpiece in the machine and watching its peration.

Two other specialized jobs found in many ma-ine shops, particularly production shops, are ose of set-up men and lay-out men. Set-up men djust and prepare the machine tools for operation y less-skilled employees. Lay-out men mark uide lines on metal so that operators can know here to machine and how much material to move.

Where Machine Shop Workers Are Employed

Because of their importance in making metal roducts, machine shop workers are employed incipally in the metalworking industries. early every industry, however, employs some achine shop workers in maintenance work. In 40, a fairly typical peacetime year, about 70 rcent of all the workers in the machine shop cupations had jobs in metal industries like achinery, automobiles, and iron and steel. From art 2 it can be seen that in 1940 the largest gle group of these workers, within the metal-rking industries, was in plants manufacturing achinery and similar products, which employed out 27 percent of the total. Second in importance was the group of industries making iron and steel and iron and steel products (such as plumbing and heating equipment, castings, and hardware), accounting for 15 percent. The automobile industry, with 12 percent, and electrical machinery plants, with 7 percent, were the next largest employers of machine shop workers.

Most of the remaining machine shop workers were found in the maintenance shops of a large number of nonmetalworking industries, including, for example, railroads, public utilities, and plants making such products as cotton textiles, paper, cigarettes, chemicals, and food. Even though the number of machine shop workers in most nonmetal industries is small, these industries, taken together, are important as a source of employment for machine shop workers since they provided almost a third of the jobs for them in 1940. Moreover, in many cases the machine shop jobs rate among the better job opportunities in the plant and its locality, as, for example, in many textile mills in southern towns.

The wartime demand for munitions resulted in a great expansion of employment in metalworking industries. The number of machine shop workers doubled, and the proportion of total machine shop workers who were employed in these industries increased from 70 percent in March 1940 to over 80 percent in December 1943. Chart 2 shows that the largest relative gain in employment of machine shop workers occurred in aircraft plants. There was also a sharp increase in the automobile industry, which during the war produced a large quantity of aircraft engines, tanks, and other munitions, as well as trucks for military use. The number of machine shop jobs in the machinery and electrical machinery industries more than doubled, most of this rise occurring in plants converted to war production. The iron and steel industry group also increased substantially its employment of machine shop workers, largely in newly built ordnance plants and in plants converted to ordnance manufacture.

The ending of the war has tended to restore the prewar status of the industries in terms of their relative importance as sources of jobs for machine shop workers. The production of aircraft, ships, and ordnance has fallen to a fraction of the wartime output, while employment gains have been made by many of the nonmetal industries whose activities were restricted during the war.

---

[1] Sixteenth Census of the United States, 1940, Population, Volume III, The Labor Force, Reports by States, Parts 2 to 5. Based on the number of males orting themselves employed as machinists, die makers, or tool makers. Excludes those employed on public emergency work.

Because so many machine shops are in metalworking industries, the bulk of them are found in the northeastern and middle western sections of the country, where these industries are concentrated. Some machine shop employment, however, is scattered throughout the country in railroad repair shops and the maintenance shops of other industries. There are machine shop jobs in every State. From the table on p. 7 one can get an idea of where the job opportunities are located.

Working Conditions

What It's Like To Work in a Machine Shop

Machine shop work cannot be described by painting a simple picture of a typical machine shop. If you think about the many industries that have machine shops and the different types of machine shops, you can see that one machine shop can be very different from the next, depending upon its size, whether it is a job shop, maintenance shop, or production shop, and what kinds of products it makes.

Shops can range from the large modern shop with long rows of machine tools busily chewing into metal, to the small maintenance shop occupying a little corner of the factory floor in which a few standard machine tools have been placed. In general, the work surroundings compare favorably with those in other types of metalworking activities.

Most machine shops are relatively clean and free from dust, compared with many steel mills and iron foundries. However, some machine shops are dirty and hot, because they are near the heat-treating or casting departments of a plant. There is usually considerable noise in a large shop. Most machine shops are well-ventilated, and good lighting is provided to aid in achieving the accuracy which is so important in machining operations. Large establishments, particularly production shops, often have overhead cranes or other materials-conveying devices.

Great physical strength is not required for machine shop work. The workers, however, usually must stand at their jobs most of the day, and be able to move about freely. Since continuous attention is required when the machine is in operation, the work may often be rather tedious, especially on simple and repetitive machining jobs. Where the work is varied and complex, and the standards of accuracy high, the worker can consider himself a real craftsman and experience the satisfaction that this feeling gives to the conscientious and capable person. Because the work is not physically strenuous, many women are employed as machine tool operators. However, most of them are employed in some of the less-skilled machining operations, practically none being found among the tool and die makers and all-round machinists and relatively few among the skilled machine tool operators.

Hazards in Machine Shop Work

The danger of serious accident in machine shops is relatively small. Workers are sometimes injured by flying chips of metal or by the sharp points of cutting tools. In cleaning away metal chips or shavings from the machine it is possible for the worker to be hurt if he is not careful. However, ordinary safety precautions are usually sufficient to keep the machine tool operator from harm. The industries in which machine shop workers are employed generally have average or better-than-average safety records, in comparison with manufacturing industries in general.

Other Conditions Affecting the Work

The great majority of machine shop workers are members of unions. There are a number of labor organizations in this field, some of the more important of which are the International Association of Machinists (independent), the United Electrical, Radio and Machine Workers of America (CIO), the United Automobile, Aircraft, and Agricultural Implement Workers of America (CIO), and the Mechanics Educational Society o America (independent).

The extent to which seasonal lay-offs can affect the employment of machine shop workers i largely dependent upon the type of industry Maintenance workers usually tend, however, t have relatively steady employment no matte which industry they are in. The automobile industry is an example of one that has usually ha marked variation in activity at different times o the year. In addition to affecting workers in th utomobile industry itself, these changes also influence the regularity of the employment in many tool and die jobbing shops which supply special dies and jigs to automobile plants.

Outlook for Machine Shop Employment

The number of jobs for machine shop workers n the future depends upon the production trends of the industries in which they are employed and also upon the effects of technological changes.

Trends in Metalworking Industries

Since metalworking industries employ by far he bulk of the machine shop workers it is to these ndustries that we must look for the chief indication of what is likely to happen to machine shop employment. Metalworking industries have many machine shop workers in maintenance jobs, but he greater number are in production jobs. The number of jobs for these workers is affected directly by the demand for the industries' products.

Prospects are favorable for a high level of activity over the next several years in the metalworking industries. Although somewhat below he wartime production peaks, the volume of output expected will be considerably above the totals n the years immediately preceding the war. Despite the fact that progress in restoring civilian production has been somewhat retarded by materials shortages and labor disputes, employment has thus far been maintained fairly well.

Many of the most important metalworking industries currently have particularly strong demands for their products. The accumulated demand for automobiles should mean that this industry, one of the largest employers of machine shop workers, will have a high volume of production for several years. The manufacturers of machinery, both electrical and nonelectrical, have a large volume of orders from companies which are expanding their productive capacity or replacing existing equipment with more efficient machinery. As construction activity continues to gain there will be heavy demands for many types of metal products used in construction. Plumbing and heating equipment is just one important example. The needs for many types of consumer goods such as electrical appliances, refrigerators, radios, and vacuum cleaners will help to keep metalworking activity at a high point over the next several years, unless a sudden drop in general business activity occurs.

Favorable employment conditions in these industries for the next several years should help to provide opportunities to get into the machine shop field, but in considering the desirability of entering this field, the long-run prospects for the employing industries are more significant. This is particularly true because many of the occupations require as much as a 3- to 5-year learning period. The conditions prevailing after the end of this training period are more important in deciding whether to begin machine shop training than are the conditions at the time of entrance into training. The long-run trends of activity in metalworking industries are related more to the basic nature of the demands for metal goods than to the temporary accumulation of demand, which is the important factor in the immediate future.

Metal goods are more durable than most other types of goods. This means that they can be used longer and that purchase of new goods to replace the old can often be postponed. A large proportion of metal products is machinery and other industrial equipment. When the business outlook appears favorable, manufacturers often buy additional equipment; when things look bad they may even hold off buying needed replacements. Because metal goods are durable and much of the demand for them is so strongly influenced by general business conditions, there have often been great variations from year to year in the quantity produced.

The trend of metal products output, although marked by extreme ups and downs, has been generally upward for many decades. Between 1899 and 1914 there was a substantial increase in activity in metalworking industries, as shown by employment trends in chart 3. During World War I there was a great jump in employment in these industries, with the big gain in shipbuilding the most important factor. After the drop in the depressed postwar year of 1921, employment in the group, stimulated partly by the strong demands for automobiles and other consumer goods, rose again until it approached 3 million in 1929.

The extremely sharp fluctuations in the trend in metalworking activity between prosperous and depressed periods are shown in chart 3 by the substantial dip in employment that occurred between the high level of 1929 and the bottom of the depression in 1932 and 1933. By 1937, employment in these industries had risen until it slightly exceeded the 1929 mark. The trend was again sharply downward in 1938, but by 1940 the long-run upward movement was resumed.

The Second World War, bringing its almost insatiable demands for production, affected all parts of the American economy, but nowhere was its influence greater than on the metalworking industries. The military machine needed vast quantities of metal munitions—ammunition, aircraft, ships, tanks, and transport vehicles. The result, as chart 3 shows, was that employment in the metalworking industries more than doubled from 1940 to 1943.

The first big jump came in 1941, when the defense program was getting into full swing, but the rise continued at an undiminished rate in 1942 and 1943 as entry into the war brought the country into a full-scale armament program.

Increases in employment occurred in all of the metalworking industry groups, but the greatest gains were made by the producers of ships and aircraft. These two industries employed a total of 155,000 production workers in January 1940; by December 1943 well over 2 million were needed to staff the aircraft plants and shipyards.

The last months of 1943 marked the high point of the war as far as employment in the metal industries was concerned. Some of the first cutbacks in munitions production, combined with the effects of drafting workers into the armed forces, caused a gradual decline in employment in these industries during 1944 and the first 6 months of 1945. With the end of hostilities in Germany and Japan, employment took a sharp dip in the fall of 1945. Since then, employment in the metal industries tended, except for the period of major strikes in early 1946, to increase slowly but steadily through the first 10 month of 1946 even though employment in aircraft and shipbuilding continued to decline.

The picture we thus have of the long-run trends in the metalworking industries is one of generally steady growth between 1899 and 1929; depressed conditions during much of the thirties, but with a high measure of recovery toward the end of that

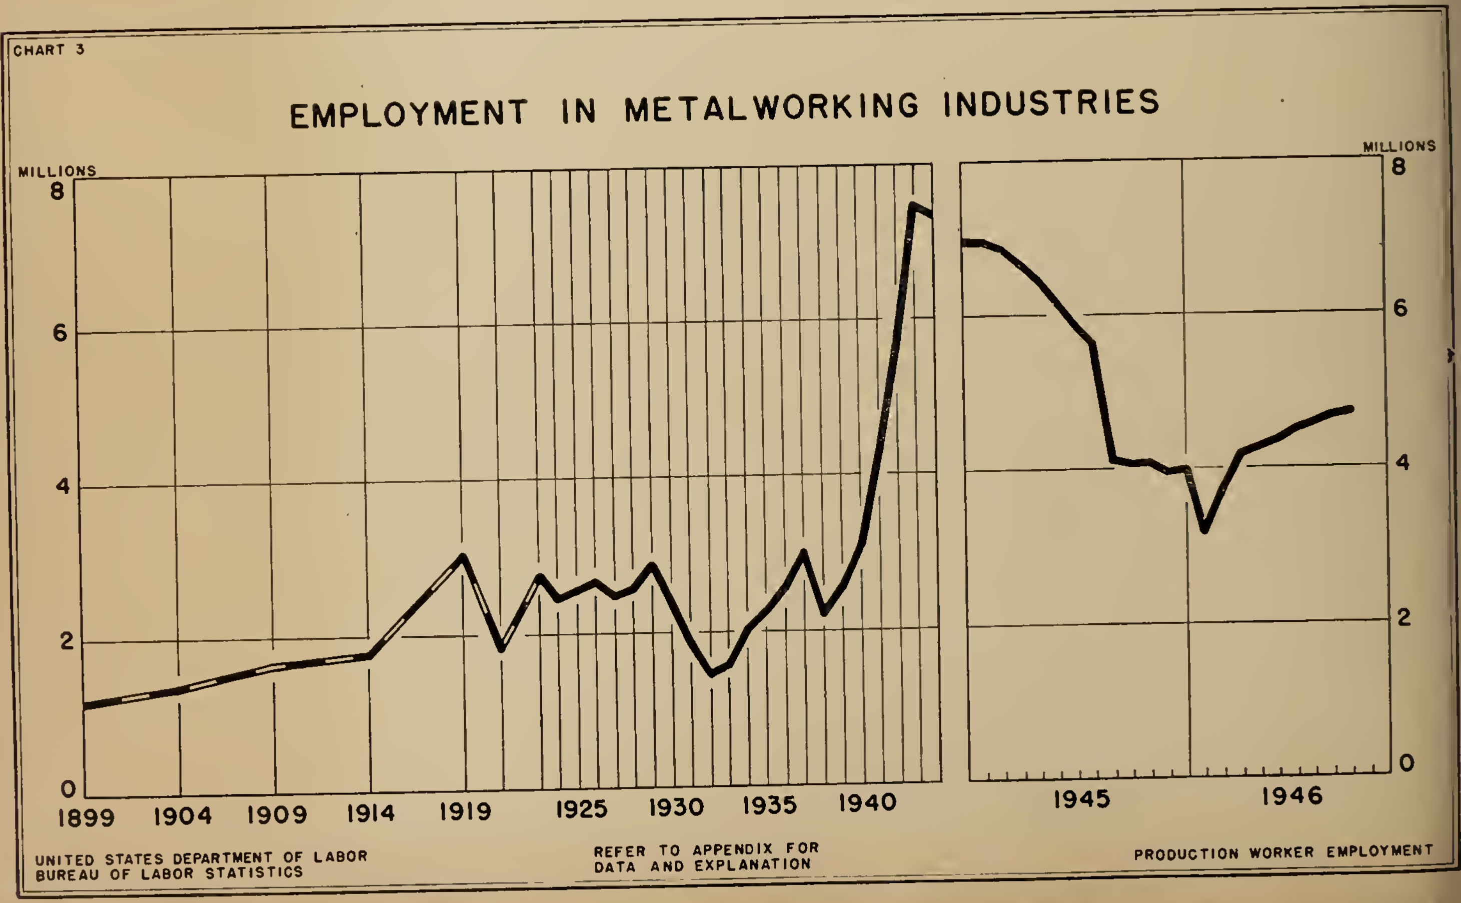

CHART 3

EMPLOYMENT IN METALWORKING INDUSTRIES

UNITED STATES DEPARTMENT OF LABOR

REFER TO APPENDIX FOR DATA AND EXPLANATION

PRODUCTION WORKER EMPLOYMENT

lecade; a phenomenal expansion during World Var II; and some postwar reduction that still eaves employment considerably above what it vas in the prewar years.

In looking at the future of metalworking it eems likely that with continued growth of popuation and national income, and development of ew products, a long-range upward trend in the olume of output is in prospect. Metal products vill continue to be an important part of total ndustrial production, and there is nothing to inlicate that the upward trend in metalworking acivity has reached its limits. New uses for metal re constantly being found, and the mechanizaion of industry (which requires metal equipment) s continuing. Some of the substitutes for metal roducts, such as plastics, compete effectively with netal only for certain uses. It must be rememered, however, that, as shown in chart 3, the netal industries have been severely affected by usiness depressions.

Outlook for Machine Shop Workers in Nonmetal Industries

Although only a relatively few machine shop vorkers are employed in any single nonmetal acivity, such as textile manufacturing, oil refining, voodworking, or trade and service, taken as a vhole these fields provide a substantial number of nachining jobs. Since the machine shop workers n these industries are engaged in maintenance vork, repairing and replacing parts of machines nd other equipment, the number employed in a articular industry does not necessarily vary diectly with its output. Machine shop workers are sually only a very small part of the total emloyment in a nonmetalworking industry. In eneral, employment of maintenance workers in n industry tends to remain fairly constant over hort periods but moves upward or downward with ubstantial changes in the volume of production. n most industries, a certain number of mainteance workers is needed even when production alls to very low levels.

There are some nonmetal industries whose needs or machine shop workers are closely related to he volume of production. An example of this is lastics fabricating, which uses machine shop workers to make the molds in which many plastic products are formed.

Prospects are good for a rise in machine shop jobs in nonmetal industries in the next several years. Many of these industries are increasing their output to take care of the strong demands for their products, as the consuming public, with employment and pay-rolls at high levels, rushes to the stores to buy food, clothing, shoes, and other nonmetal goods. In addition, many industries were unable to keep enough machine shop workers during the war and will try to hire more to have the number needed for efficient operation.

An important point affecting the long-run requirements for machine shop workers in these industries is that increased mechanization of plants, although tending to reduce the needs for other employees, creates more jobs for maintenance workers. The nonmetal industries also tend to be more stable in their rate of production, and maintenance has a fixed importance in their operation. This means that these industries will continue to offer regular employment to a large number of machine shop workers.

Effects of Technological Changes on Machine Shop Employment

It is characteristic of industrial operations that there is a continual striving to find ways of increasing efficiency and thereby reducing production costs. This effort leads to better ways of organizing production and to the introduction of new machines which are faster, larger, and more automatic in their operation. Thus the tendency in all manufacturing operations is to cut the amount of labor time needed to produce a given part.

These improvements, while reducing the employment required for a certain volume of output, do not necessarily result in a lowering of total employment needs. Very often by reducing costs and, in turn, prices, it has been possible to reach a wider market of potential consumers, and thus increase production more than enough to offset the reductions in labor requirements. In this way, although many products take fewer man-hours per unit to produce than they did years ago, many more people are now employed in their manufacture.

Technological changes cannot, however, be ignored in considering the prospects for employment in any particular industry or occupation. This is because they affect the amount of employment which will result from a given volume of production in the future. In the case of machining processes, there have been many recent technical changes which may have an important effect on the number of jobs there will be for machine shop workers. During the war, under the necessity of increasing rapidly the output of metal products, the development of new machines and techniques was intensified and hastened. Many of these developments should carry over into the future with even greater force.

The greatest reductions in labor costs usually come through the introduction of new types of machinery. In the machine shop field, increasing use has been made of highly automatic, special purpose machines. These machines are designed to perform one particular operation, and are used when large quantities of parts are needed. In addition to providing for high speed and efficient operation they usually eliminate much of the skill needed by the operator.

Another important technical development which is greatly influencing the number of man-hours needed in machining processes is the growing use of high-speed carbide cutting tools. Because these cutting tools are harder, it is possible to machine metal with them at much higher speeds than formerly were possible. Consequently the rate at which machine tools dig into metal has been increased in many cases as much as from 3 to 5 times. This has resulted in substantial reduction of the time required to machine many parts. Many of the older machine tools are unable to operate effectively at the high speed made possible by the development of these new cutting tools, but new machine tools, which are heavier and stronger than the older ones, will make it possible to utilize more fully the new higher speeds.

Among the other changes in machine tools which may affect the time required for many machining operations or the skills required of the operator are the use of electronic controls and hydraulic mechanisms.

Greater use may be made in the future of profiling attachments. When these are used the movement of the cutting tool is guided by a rod which as it moves along follows the shape of a model of the desired object. On these machines intricate objects can be shaped by partially skilled operators, and one operator can control a number of machines simultaneously.

In addition to changes in machinery, changes in the organization of machine shop processes can also influence the number of workers and the types of workers required. One important innovation has been to use set-up men to adjust machine tools, turning over the rest of the operation to semiskilled operators. In other ways, jobs have been subdivided so that the difficult parts can be done by skilled operators, while the more routine steps can be performed by less-skilled operators. Another method by which machining time can be reduced is to begin the machining operation on pieces of metal that are already close to the dimensions of the part being made. This can be done by working from a casting or forging of the part, rather than from a rough bar or block of metal. Technological advances in casting and forging, making these processes more precise or economical, would encourage their use in some cases where rolled shapes have previously been used. In addition, when castings or forgings are made with greater precision, the amount of machining required to turn out the finished part is reduced.

Still another way that technological changes can affect machine shop employment needs is through the substitution of other processes in fabricating operations which have usually been done by machining. This can come about through the greater use of stampings, die castings, or plastic parts in place of machined parts. There is also some possibility that powder metallurgy, by which metal products are pressed into shape from powdered metal, may become more important Since machining is an expensive process, industries can be expected to continue the attempt to obtain precision parts by the use of other methods.

Future Trends in Machine Shop Employment

Taking into account the production prospect of the industries which employ machine shop workers and the probable effects of continuing technological changes it would appear that the numbe of machine shop jobs should be maintained at o slightly above the present high levels for severa years. Looking further into the future the indi tions are for an employment trend below both the gh points of the war period and the levels that ould prevail in 1947, but employment should main considerably higher than the prewar levels. ventually, the general long-run upward move- ent of metalworking activity should be resumed, d this would tend to raise machine shop em- oyment. Because the machine shop field is so osely related to metalworking, however, employ- ent in machine shops is likely to be especially rd hit by severe business depressions.

The incentives to reduce the costs of producing unit of product will be no less strong in the ture than in the past. Current and prospective chnological changes will bring about further lative reductions in the number of man-hours quired for machining. Not only will the amount labor required to machine a given part be less, but the present tendency to utilize a larger proportion of less-skilled operators instead of skilled all-round workers will continue with even greater effect.

The generally favorable trend of employment in machine shops means that qualified new workers should be able to enter the field without much difficulty in the next several years and be assured of continuing employment. Before deciding whether to go into machine shop work, it is necessary to get a complete picture of the opportunities in this field in order to have an idea of the relative prospects of the individual occupations. For this reason the outlook for each of the significant occupations in machine shops is presented in detail in the following sections of this report, along with a discussion of duties, qualifications, training, earnings, and other information on the occupation.

Opportunities in Individual Occupations

All-Round Machinists

The job of all-round machinist requires a knowl- lge of all the machine shop skills necessary to ake and repair metal parts for all kinds of ma- iinery and metal equipment. Historically, this aft is the basic and original machine shop occu- ition; as division of labor progressed in some pes of shops, workers began to specialize in one another of the tasks of the all-round machinist, d the other machine shop occupations developed.

At the peak of wartime employment, in De- mber 1943, about 170,000 men were working as l-round machinists. There were, in addition, ousands of men with training as all-round achinists but employed in other machine shop cupations, such as set-up man, lay-out man, and achine tool operator.

Duties

Variety is the main feature of the all-round achinist's work. His training enables him to an and carry through all operations needed in rning out a machined product and to switch adily from one kind of product to another. He iows how to work from blueprints and written ecifications, can select the proper tools and ma- rials required for each job, and can plan the oper sequence of cutting and finishing operations. When necessary, he lays out the work by marking the surface of the metal to show where machining is needed and to indicate the shape and depth of the cuts. In laying out work he uses a number of marking tools and measuring instruments, including the scriber, center punch, surface gage, protractor, and calipers.

In general, he is able to set up and operate such standard machine tools as lathes, planers, milling machines, grinders, shapers, boring mills, and drilling machines. In setting up machine tools for operation, the machinist must be expert in a number of details relating to both the machines and the cutting tools. He selects the proper cutting tools necessary for each cut he is to make, fastens the cutting tools and the work in proper relation to each other, and sets controls which determine the sequence of cutting tools if there are more than one, the speed at which the tool or work moves, and the depth of the cut with each motion. When the machine is ready to be operated, he makes a sample cut and checks the accuracy of the set-up with such precision measuring devices as gages and micrometers. After machining, he may finish his work by hand, using files and scrapers, and may assemble the parts by welding. His knowledge of shop practice, of the working properties of such metals as steel, cast iron, aluminum, and brass, and of what the various machine tools do makes it possible for him to turn a block of metal into an intricate, precise part.

Training

The machinist trade can be learned in two ways. According to most authorities, a formal apprenticeship, usually covering 4 years, is the best way to learn the job. On the other hand, many have qualified without an apprenticeship, picking up the machinist trade over a number of years of varied shop experience and home study. However, this takes a longer time than apprenticeship and the training may be incomplete.

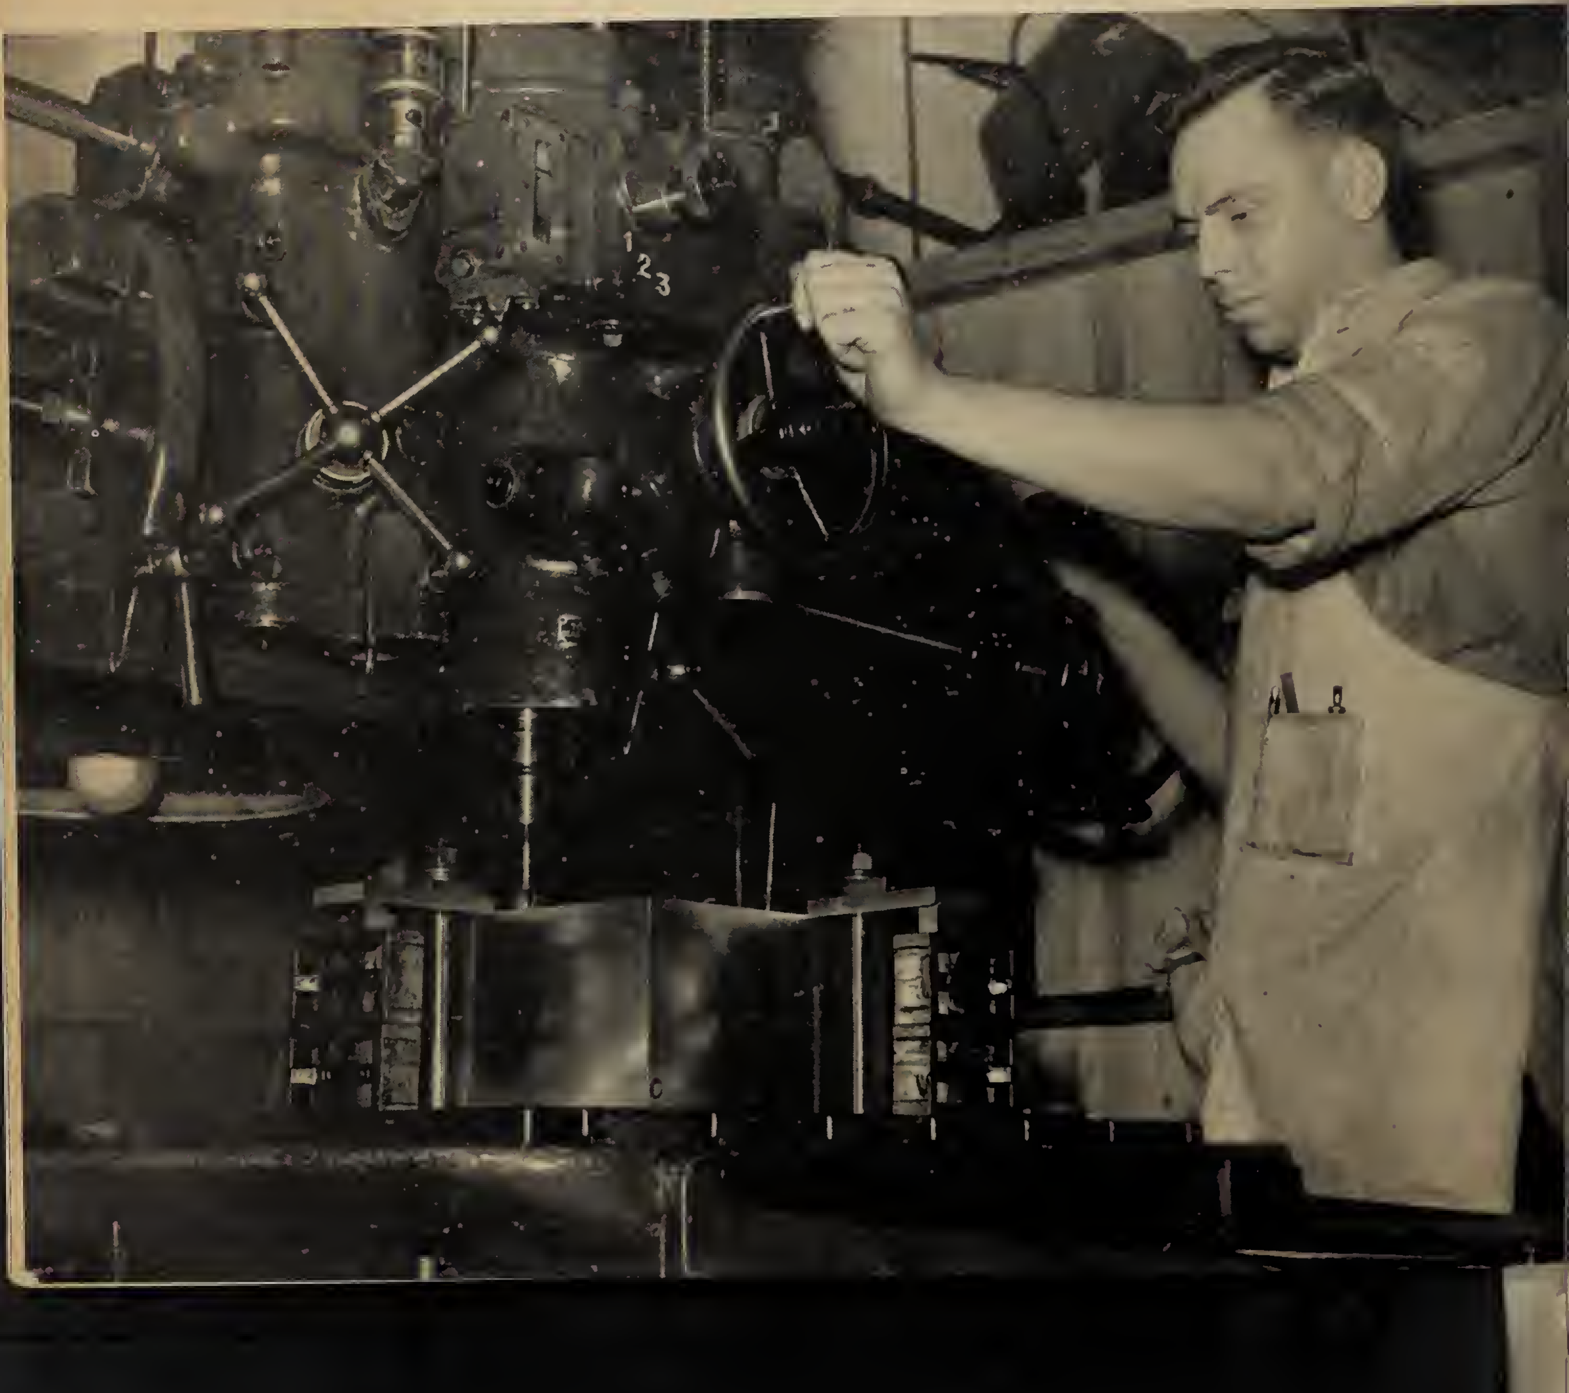
An apprentice must be mechanically inclined and be temperamentally suited to very careful and exact work; otherwise he will be handicapped in his training. Another important aptitude necessary to become a machinist is an ability to visualize the finished product from a rough drawing or blueprint. A high school or trade school education is desirable preparation for machinist training, and some employers require such preparation.

Where Employed

The majority of all-round machinist jobs are in maintenance shops in plants which use machinery in the manufacture of their products, such as textile mills, automobile factories, oil refineries, and

Machinist using a boring mill to machine a hole in a gear box. The boring mill is one of a number of machine tools which an all-round machinist can operate.

DEPARTMENT OF LABOR PHOTO



inting plants. Many of these all-round jobs are so found in manufacturing shops (including b and production shops) which make machinery id metal parts, such as machine tools, tractors, id railroad equipment. In general, work in job id maintenance shops is more diversified and quires greater all-round skill.

In production shops such as those found in the tomobile and electrical appliance industries, ere are large numbers of men trained as all-und machinists but not usually employed as ch; these men specialize in a single machine shop nction, such as lay-out, set-up, or operation of ie type of machine tool. As a result, they may time partly lose the other skills which they had quired in becoming machinists. However, they e still much more versatile than those without achinist training, and if necessary, they can adily relearn that which was lost through lack practice.

Employment Outlook

The number of all-round machinist jobs during e next few years should equal, or even exceed, e wartime peak, because of the increased need r machinists in maintenance shops, where the ilk of these jobs are found. Many nonmetalorking industries were affected by wartime curilment of production or by labor shortages id consequently did not employ as many machins in their maintenance shops as might otherwise ve been expected. Since some of the largest of ese industries, such as textiles, have very favorle postwar prospects, they should be taking on achinists for several years. In manufacturing ops as a whole, there will be somewhat fewer l-round machinist jobs than during the war. owever, these shops will need additional men th machinist qualifications to work as skilled, ecialized machine tool operators and as set-up en. They will also hire all-round men to prode for their future needs for supervisory orkers.

Openings for apprentice machinists should be merous during the next 2 or 3 years although any have already begun training. It must be reembered, however, that in the metalworking instries many of these apprentices, after they comete their training, will be placed in specialized bs where they will work on only one type of achine.

Employers will be taking on apprentices because they realize that many new men must be trained if even the present number of machinists is to be maintained. Owing to the depressed condition of industry before the war and the difficulties in training apprentices in wartime, relatively few entered the trade over a period of many years. Now there are many all-round machinists closely approaching the age when death or retirement will take them from their jobs. To provide for their replacement, it is conservatively estimated, over 40,000 new machinists must be trained during the next decade.

Apart from job prospects for the immediate future, there are longer-run employment trends to be considered. In manufacturing shops the number of jobs requiring all-round machinists to fill them may be expected to show a slight, gradual decline after the next several years. Continuing technical changes will reduce the skill needed in many machining operations, permitting the substitution of less-trained men for machinists. Machinist training will continue, however, to offer considerable advantage to men going into these shops. Machinists are generally preferred for the specialized machine tool operator jobs, which often pay as well or better than all-round jobs. They also will have many chances to get jobs setting up machines for groups of semiskilled operators. Moreover, all-round machine shop workers must continue to be hired in order to supply the necessary supervisory staffs—the lead men and foremen—which are extremely important in the modern mass-production shops where there is a large proportion of workers with a narrow range of skill.

In maintenance shops, the number of all-round machinist jobs should remain fairly steady, and may even show some growth over a period of many years. The increasing mechanization of industry will expand the need for men to keep production equipment in good working order, and this may mean more jobs for maintenance machinists.

Earnings

Although the pay of all-round machinists compares favorably with that of other machine shop workers, it is often lower than the earnings of highly skilled machine tool operators, many of whom work on an incentive basis. In January

1945, average straight time hourly earnings of production machinists in some of the major metalworking industries were as follows: Machine tools, $1.13; tool and die jobbing shops, $1.22; other machinery (except electrical machinery) industries, $1.19. Maintenance machinists earned about the same, or slightly more. Since that date, there have been substantial wage increases in many industries employing machinists. For example, in early 1946, hourly rates in some of the largest automobile companies were raised 18 or 18½ cents.

Chances for Advancement

The promotional opportunities for all-round machinists are good. Many advance to foreman of a section in the shop, or to other supervisory jobs. With additional training some develop into tool and die makers. Highly skilled and experienced machinists sometimes have the chance to start small machine shops of their own.

Tool and Die Makers

Tool and die makers are essentially highly trained machinists who specialize on tool or die work. Theirs is the most skilled job in machine shops and is also one of the larger skilled fields in metalworking—about 90,000 were employed at the wartime peak in December 1943.

Duties

The function of tool makers is to make the cutting tools used on machine tools, and the jigs, fixtures, and other accessories which hold the work while it is being machined. They also make the gages and other measuring devices needed for precision work. Die makers construct the dies which are used in such metal-forming operations as forging, stamping, and pressing, and they also make the metal molds used in die-casting metal and molding plastics. Tool and die makers must have the broad knowledge of the all-round machinist, including blueprint reading, laying out work, setting up and operating machine tools, using precision measuring instruments, understanding the working properties of common metals and alloys, and making shop computations. In addition, they must be able to work to closer tolerances than those usually required of machinists and mus do a greater amount of precise hand work. These requirements, plus specialization on tools and dies distinguish tool and die makers from all-round machinists.

Apprentice tool and die maker using a shaper to form a die part. Tool and die makers know how to operate all standard machine tools.

DEPARTMENT OF LABOR PHOTO.

Training

To learn this work requires rounded and varied machine shop experience, usually obtained through formal apprenticeship or the equivalent in othe types of on-the-job training. A tool and die apprentice ordinarily covers 4 or 5 years, includin mainly shop training in various parts of the job In addition, during the apprenticeship, course such as shop arithmetic and blueprint reading ar usually given in vocational schools. After apprenticeship, a number of years of experience a a journeyman is often considered necessary t qualify for the more difficult tool and die work.

Since tool and die making is the most exactin type of machine shop job, persons planning to enter the trade should have a great deal of mechanica ability and a liking for painstaking work.

Where Employed

Although tool and die makers are employed i many different metalworking industries, a larg proportion of the jobs are concentrated in a relatively few industries. Of these, the automobi industry is the most important. Also very important, both because of the number employe and because of the high level of skill required o the workers, are tool and die jobbing shops. The ops, which usually are small, make tools, dies, gs, and fixtures, and other machine tool acces- ories for other companies on individual order; e tool and die makers in these shops must be ble to take on almost any kind of job. Many ol and die makers are employed in other machin- y industries, including those making electrical achinery. During the war the aircraft indus- y hired many tool and die makers. Among the onmetalworking industries that use these work- s is the fabricated plastic products industry, hich employs die makers to make the molds in hich plastic products are formed.

Employment Outlook

The biggest factor in the job outlook for tool d die makers, in view of the fact that the auto- obile industry is the most important single em- oyer of these workers, is the expected large vol- e of automobile production. High output of tomobiles will also tend to maintain employment tool and die jobbing shops, many of which serve e automobile industry and which are another ajor source of jobs in this occupation. In many her peacetime industries—such as the refrigera- r, electrical appliance, and agricultural machin- y industries—production prospects are good, d this will contribute to the demand for tool d die makers. Moreover, the tooling up for the w products which numerous firms are planning manufacture will provide tool and die maker bs, since new dies, jigs, fixtures, and gages will required.

In spite of the upward trend of employment many industries using tool and die makers, the tual number of jobs in the occupation may be higher than the wartime total. The reason for is is the dropping off of aircraft and ordnance oduction, which during the war provided jobs many tool and die makers. Nevertheless, op- rtunities in tool and die making should be good, cause there has been little increase in the supply fully qualified tool and die makers in recent ars and because replacement needs have been owing in importance.

During the war the number of tool and die akers increased, but not as rapidly as some other etalworking jobs, partly because it was not pos- ble to train qualified tool and die makers in the ort time available. As a substitute, much tool and die work was broken down into simpler jobs which less-experienced workers could do under the supervision of tool and die makers. At the same time, working hours were greatly increased. However, although these were useful wartime expedients, most employers do not consider them satisfactory for peacetime and strongly prefer using fully qualified men, working a standard week. As a result, there is a demand for trained tool and die makers in many plants. Although many apprentices have been taken on since the end of the war, openings should continue to be fairly numerous for several years.

Replacement needs are an important factor, because many tool and die makers are approaching ages at which they are increasingly likely to drop out of the labor force because of death or retirement. During the next 10 years, such drop-outs may create upward of 20,000 openings for new workers.

After several years, the accumulated demand for automobiles, electrical appliances, and similar consumer goods will have been met and the employment of tool and die makers will probably drop slightly from its high postwar level. However, large numbers of these workers will still be needed, not only to repair and replace the tools and dies normally used by industry, but also to retool plants for new models and new products. Moreover, although improved metalworking equipment will tend gradually to cut down the number of machine shop jobs, tool and die makers, because of their role in making the tools and dies needed to produce and use this equipment, will be less affected than other machine shop workers. It is also unlikely that technical advances will very much reduce the skill needed in this occupation. Finally, the trends toward greater use of die casting, stamping, and plastics molding will tend to increase die maker employment in connection with these processes. These factors, as well as continuing replacement demand, make it reasonably certain that those who enter the trade during the next several years will find good employment opportunities for many years to come.

Even in the event of a general business depression, with machine shop employment temporarily falling to a low level, experienced tool and die makers, because of their all-round skills, would have fairly good chances to get lower-rated machine shop jobs. Thus, from the point of job security, they may have a considerable advantage over other machine shop workers.

Earnings

Tool and die makers are the highest-paid machine shop workers. In January 1945 their average straight time hourly earnings were $1.55 in tool and die jobbing shops, where skill requirements tend to be highest but where employment often varies greatly from season to season. In the machine tool industry during the same period, they averaged $1.35 an hour. Tool and die makers employed in plants making other types of machinery were earning $1.29 an hour, straight time. Wages in these industries have been increased since the date mentioned.

The earnings of tool and die makers vary widely among areas. For example, those employed in tool and die jobbing shops in the Detroit area were averaging approximately $1.75 an hour in January 1945.

Chances for Advancement

Tool and die makers often rise to better jobs. Many have advanced to shop superintendent or other responsible supervisory work, or to such positions as tool designer. Another avenue of opportunity is the opening of small tool and die jobbing shops.

OWI PHOTO BY HOLLEM.

Machine Tool Operators

By far the greatest number of machine shop workers are employed as machine tool operators. Their employment at the wartime peak reached an estimated 910,000, or more than 75 percent of the total in machine shop occupations. Unlike the all-round machinists with whom they are often confused, machine tool operators usually work on a single type of machine tool, such as a lathe, milling machine, planer, or shaper, and most of them cannot carry a job through all its different stages.

Duties

Machine tool operating jobs may be divided into two main classes, according to the skill required. The skilled machine tool operator does widely varying kinds of machining. Working from blueprints or lay-outs, he sets up his machine for each machining operation, adjusts the feed and speed controls, and measures the finished work to see if it meets specifications. He knows how to sharpen cutting tools when they become dull and understands the machining qualities of various metals. In brief, his work is very much like that of the all-round machinist, except that it is limited to a single type of machine tool.

The majority of machine tool operators are much less skilled than the machine tool specialists described above and do work which is repetitive, rather than varied. A typical job of one of these workers consists mainly of placing rough metal stock into an automatic machine tool, watching the machining operation for signs of trouble, and measuring the finished work with specially prepared gages which simplify measurement. He may make minor adjustments to keep the machine tool in operation, but must usually look to more-skilled men for any major adjustments that may be needed. For each machining operation, a skilled machine tool specialist, set-up man, or machinist installs the cutting tools and sets the controls, and after a trial cut turns over the actual running of the machine tool to the operator. Some operators have slightly more responsible jobs in that their work is less repetitive and greater accuracy is required of them.

Machine tool operators, skilled and semiskilled alike, are designated according to the kind of mahine tool which they operate—for example, en- ine lathe operator, turret lathe operator, drilling nachine operator, grinding machine operator, nilling machine operator. There are many other inds of machine tool specialists, each of whom nows his particular machine tool.

As shown in chart 1, the various machine tool ccupations differ greatly in the number of work- rs employed. Among the more important of hese occupations are lathe operators, grinding nachine operators, drilling machine operators, nilling machine operators, and screw machine op- rators. The operation of other types of machine ools—such as boring mills, shapers, planers, and ear cutters—constitutes a smaller field of em- loyment. There are also differences in the pro- ortion of skilled jobs, as against semiskilled, ound in connection with the various kinds of ma- hines. For example, a relatively large number of ngine lathe operators are classed as skilled. In ontrast, relatively few grinding machine opera- ors are so designated.

Training

As one would expect, the training of the two nain classes of machine tool operators differs reatly. The skilled machine tool specialist is rained on the job, although formal apprentice- hips are not provided in this occupation. It is sual to begin as a learner in a machine shop and o spend from 1½ to 3 years on a particular nachine tool. In addition to machine work, train- ng may include instruction in blueprint reading, hop arithmetic, and similar subjects. Many em- loyers take only high school or technical school raduates as learners. Although the training of he specialist is shorter and much less varied than hat of the all-round machinist, the trained special- st is able to operate a single type of machine tool s well as any machinist. Unlike the machinist, f course, he has experience on only one type of nachine. However, many men who completed nachinist apprenticeships are employed as skilled nachine tool operators.

On the other hand it is much quicker to learn to e a semiskilled machine tool operator. Although high school or trade school education is con- idered desirable, it is not essential. In general, n-the-job training of not more than 6 months s sufficient to qualify for this kind of work.

Where Employed

Although skilled machine tool specialists are employed in all types of machine shops, most of them work in production shops. The proportion of these specialists varies greatly among production shops, however, depending on the extent of job break-down and the kind of machining done. They form a smaller percentage of the workers in job and maintenance shops, where an all-round knowledge of machine shop practice is generally preferred. Nevertheless, a substantial number of skilled operators are employed in these shops, working under the guidance of all-round machinists.

The employment of semiskilled machine tool operators is confined mainly to production shops and is concentrated particularly in such mass production industries as automobiles and radios. Because of their limited training, few can be used in either job or maintenance shops. In production shops, under close supervision, they can efficiently do routine work and free more-skilled men for the complex work.

Employment Outlook

In the next few years, job prospects for skilled machine tool specialists are likely to be good. The number trained in this work during the war is not large compared to the needs of the expanding peacetime industries, such as automobiles and electrical appliances. Possible shortages of all-round machinists may also tend to create openings for skilled specialists. In addition, some employers will continue to train specialists in preference to training all-round men, because it costs less. As a result of these factors, there should be opportunities for beginners to learn the work.

Over a longer period, the growth of specialization in machine shop work, a development greatly speeded by the war, will surely continue. This trend may offset technical advances which otherwise would reduce the need for skilled operators.

The employment outlook for the semiskilled operator is less favorable. Peacetime employment of these workers will be high, but it is hardly expected to approach the level of the war years, when large numbers were hired by metalworking industries and hurriedly trained. Many of these wartime workers were women who have since returned to their kitchens and teen-agers who have gone back to school. However, in most areas there are likely to be more experienced workers than jobs of this type and, therefore, few openings for trainees.

Those who do get jobs as semiskilled operators have fairly good prospects for continued employment in the future. The gradual simplification of machine tool work through greater use of automatic machines may widen their field of employment. On the other hand, technical advances which increase the efficiency of machine tools will tend to hold down the total number of jobs in this occupation.

Earnings

Many machine tool operators, especially the less-skilled operators, are paid on an incentive basis and hence often earn as much as machine shop workers of greater skill. In January 1945, average straight time hourly earnings of men working as first class (A) operators in the machinery industries (excluding tool and die shops and plants making electrical machinery or machine tools) were as follows, by type of machine tool: Engine lathe and milling machine, $1.16; grinding machine, $1.20; and turret lathe, $1.17. Second class (B) operators of these machines averaged from 4 to 13 cents an hour less. Third class (C) operators earned, on the average, from 9 to 15 cents an hour less than second class.

Chances for Advancement

Skilled machine tool specialists may be promoted to such jobs as set-up man or supervisor (on machines on which they have specialized). If they can get experience on several different kinds of machine tools, they also can develop into all-round machinists. Semiskilled operators generally have little chance for advancement since they are employed mainly in production shops, where the work is very repetitive and where there are few opportunities to develop additional skills.

Set-up Men

The set-up man is a skilled specialist employed in machine shops which carry on large-volume production. His job is to install cutting tools and adjust the controls of machine tools so that they can be run by semiskilled operators. This is one of the smaller machine shop occupations—about 20,000 were employed as set-up men at the wartime peak in December 1943.

The usual practice is to assign a set-up man to a number of machine tools, which are often of one type, such as the turret lathe. The set-up man works from blueprints, written specifications, or job lay-outs in order to set the cutting tools in place and to adjust, for each machining operation, the guides, speed and feed controls, working tables, and other parts of machine tools. After setting up and adjusting a machine, he makes a trial run to see if it is working properly, and then turns it over to the regular operator. During the machining operation he makes all important adjustments needed for accurate production.

In order to become a set-up man, it is usually necessary to qualify first as an all-round machinist or as a skilled machine tool specialist, since the job requires a good background in machine shop practice as well as a thorough knowledge of the operation of at least one type of machine tool. In many cases, a man obtains the needed experience through working in job shops and then gets a set-up job in a production shop.

The employment outlook for set-up men is favorable for the next few years, because of the expected high production of metal products and because of the shortage of operators qualified to set up their own machines. Over a longer period, the trend toward specialization in machine shop work will tend to provide continued employment.

Earnings in this occupation compare favorably with those of all-round machinists. In January 1945 average straight-time hourly earnings of set-up men in some of the important industries employing them were as follows: Machine tools. $1.34; tool and die jobbing shops, $1.13; other machinery industries, $1.17.

Lay-Out Men

The lay-out man is a highly skilled specialist whose job is to make guide marks on metal before it is machined to indicate to the machine operators the kind of machining needed. This is not a large occupation; at the peak of wartime employment there were only about 10,000 jobs of this type.

Working from blueprints or written specifications, the lay-out man marks guide lines, reference points, and other instructions to operators on rough castings, forgings, or metal stock. He uses a wide assortment of instruments, including the scriber, with which he marks lines on the surface of the metal; the center punch, used to indicate the centers on the ends of metal pieces to be machined or drilled; the keyseat or box rule, used

or drawing lines and laying off distances on
urved surfaces; dividers, for transferring and
omparing distances; L- or T-squares for deter-
ining right angles; and calipers and micrometers
or accurate measurement.

Not only must the lay-out man work with ex-
reme accuracy, but he has also to be familiar with
he operations and uses of each of the standard
achine tools. In general, it takes from 6 to 10
ears to develop this skill, including the machinist
pprenticeship or equivalent training needed to
arn the fundamentals of machine shop practice.
high-school education, including courses in
eometry, trigonometry, and mechanical drawing
often required; additional preparation in a trade
r technical school is considered desirable.

Like other specialized machine shop workers,
y-out men are employed mainly in production
hops. Some are also found in job and mainte-
ance shops, particularly in the former.

Employment opportunities for lay-out men are
kely to be very good for a long time to come.
he trend toward employing skilled lay-out men
conjunction with semiskilled machine tool op-
rators in production shops is expected to continue,
articularly in view of a possible shortage of ma-
hine shop workers able to make their own
ay-outs.

DEPARTMENT OF LABOR PHOTO.

Laying out a flange. This job requires blueprint reading, a broad knowledge of machine shop work, and the skillful use of marking and measuring instruments.

Getting a Machine Shop Job

Opportunities for Training in Machine Shop Work

The necessary training for machine shop jobs can be obtained in several different ways. The method used depends on which particular occupation is the goal and on the kind of training available in the community.

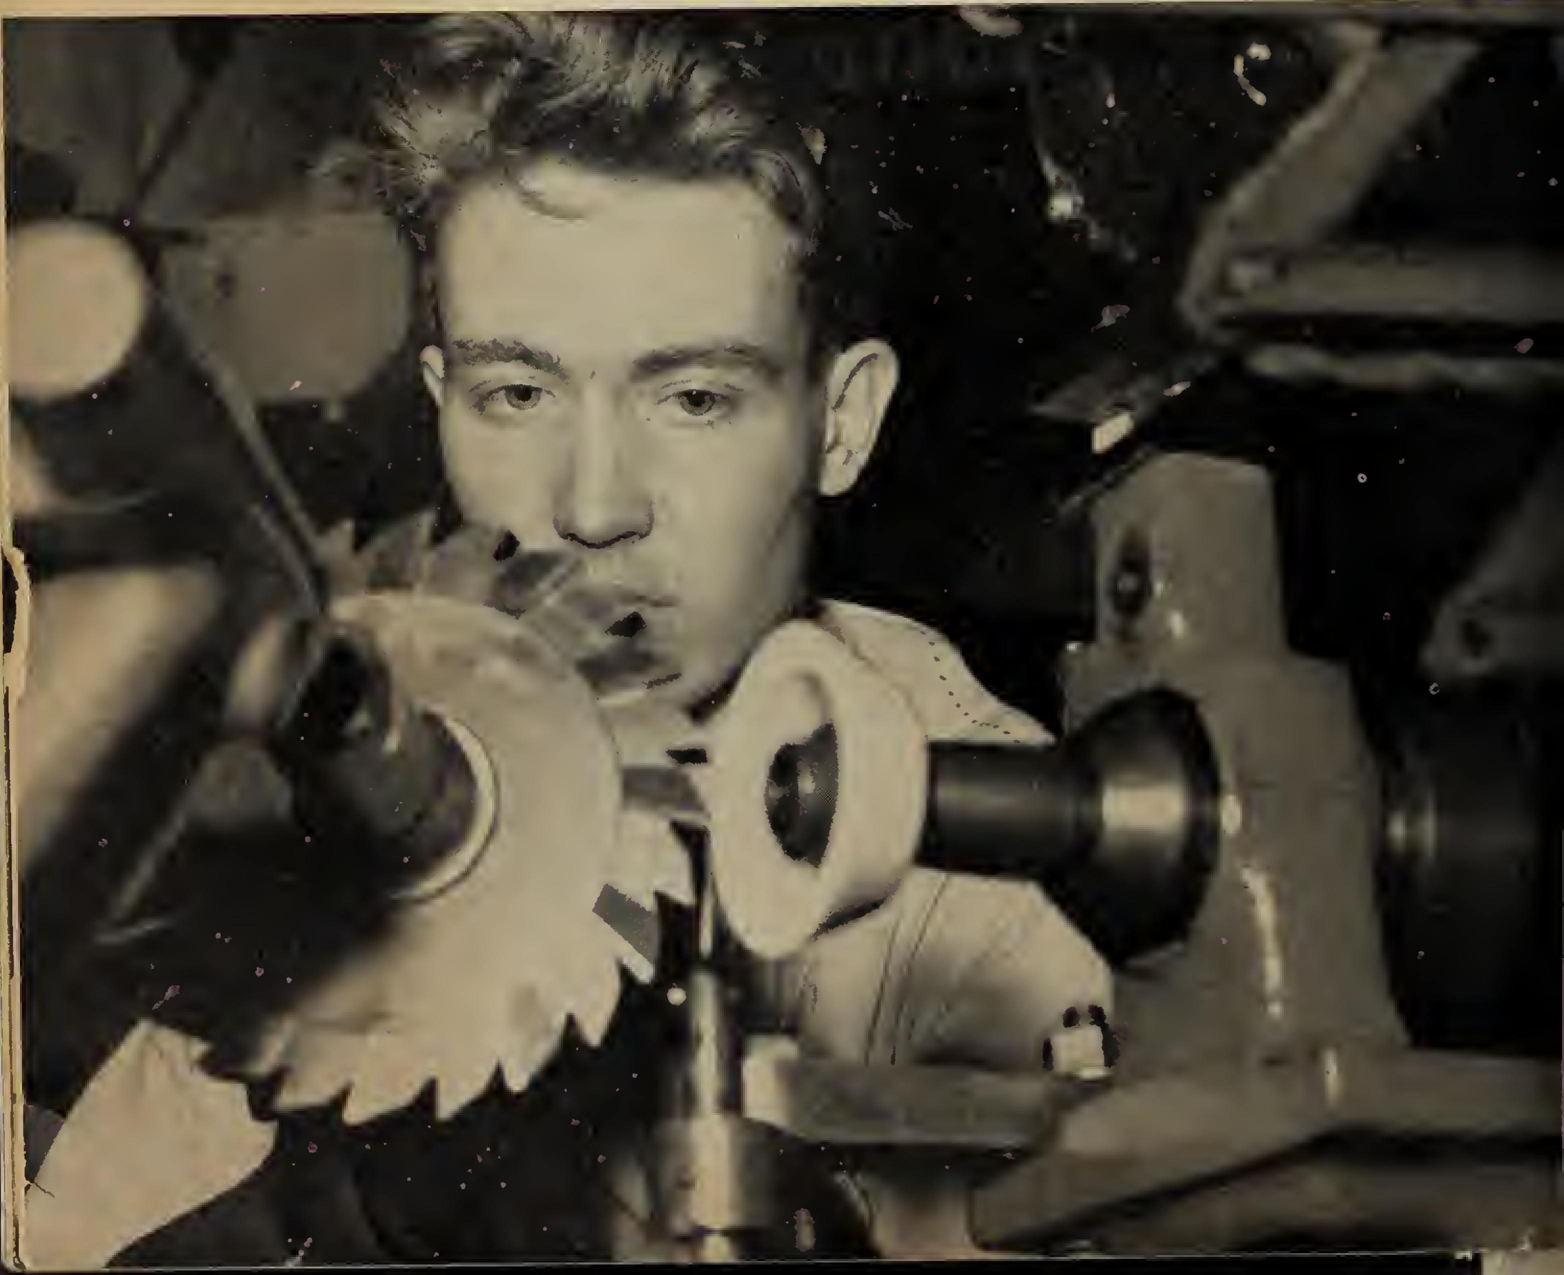
Apprenticeship

The main route to skilled jobs in machine shops is apprenticeship, in which a young man is hired with the purpose of teaching him a trade through working along with, and under the guidance of, experienced craftsmen. In a formal apprenticeship, a written agreement is made between an employer and an apprentice providing that the apprentice receive thorough training in the trade and setting forth the conditions of the apprenticeship.

Typical agreements specify a term of apprenticeship for machinists of not less than 8,000 hours

Apprentice machinist sharpening a milling cutter on a grinder. Learning to sharpen cutting tools is one part of the varied training given apprentices.

DEPARTMENT OF LABOR PHOTO.



f employment—usually extending over 4 years—nd of 10,000 hours, or 5 years, for tool and die akers. The first 1,000 hours of employment are sually a try-out period during which the agree- ient may be canceled at the request of either party.

The standards of apprenticeship are usually set p by representatives of employers and employees ho are familiar with the minimum training that s necessary in the occupation. In setting up a raining schedule, consideration is given to the ype of work being done in the shop in which the pprentice is employed and the facilities available or training. A typical work program for ma- hinist apprentices involves up to 2,000 hours of ork on lathes, and up to 1,000 hours on each of uch machine tools as the grinder, boring mill, and illing machine. It also includes lay-out work, ssembly, heat treating, and welding. Tool and ie apprenticeships are similar, but in addition equire considerable work on dies or cutting tools.

Apprenticeship agreements also provide for bout 12 hours a month of classroom instruction in elated technical subjects, such as mechanical rawing, shop mathematics, and properties of etals. This instruction may be given within the lant where the apprentice works or in a local rade school.

Although the usual term of apprenticeship is or 5 years, the period can be shortened under cer- ain conditions. Men working in lower-grade achine shop occupations, such as that of machin- st helper, can sometimes transfer to an apprentice lassification and have their experience credited oward completion of the apprenticeship. Vet- rans may be able to get similar credit for machine hop experience in the armed forces. In some ases, trade school courses also may be used in this ay.

In selecting young men for apprenticeships, em- loyers take account of their records in school, heir physical condition, and their moral character. raduation from high school is often required, nd courses in high school mathematics, physics, nd machine shop work are considered desirable reparation. Usually the minimum age for ap- rentice jobs is 16, and the maximum, 23. How- ver, this maximum age limit does not gen- rally apply to veterans. Sons of machinists or ool and die makers frequently receive preference or apprentice openings.

Earnings of apprentices usually start at from one-fourth to one-half the journeyman rate. In the course of training, their wages are periodically increased, provided progress in learning the trade is considered satisfactory. Veterans in training under the GI Bill of Rights receive, in addition to their apprentice pay, a monthly allowance from the Government of up to $65, if they have no dependents, or up to $90 if they have dependents. Combined pay and allowances, however, may not exceed the journeyman rate and may not be more than $200 a month for men with dependents or $175 a month for men without dependents. The allowance may continue for as long as 4 years. Disabled veterans can get similar assistance under the Vocational Rehabilitation Act.

Upon successfully completing his training, the apprentice is rated as a journeyman and is usually given a certificate showing this. In many cases, his employer presents him with a set of hand tools or with a cash bonus of as much as $200.

Since not all apprenticeships provide adequate training, it may be helpful for a young man considering such a job to find out if the shop making the offer has registered its program with the appropriate agency in the State or with the Apprentice Training Service of the U. S. Department of Labor. Apart from formal apprenticeships, proper training as a machinist or tool and die maker may be obtained through the programs for all-round learners provided by some companies.

Other On-the-Job Training

On-the-job instruction, other than apprenticeship, is used to train machine tool operators. In this type of training, the purpose is to produce specialists on particular machines, rather than all-round workers. Usually no formal agreement is made between the employer and the learner, as the trainee is usually called.

A learner is assigned to a single type of machine tool, say an engine lathe or milling machine. At first he works under the close supervision of an experienced operator or of a machinist, beginning with very simple tasks and gradually taking on a little more responsibility. If the learner is to be a semiskilled operator, his training period is usually over within 6 months. If, on the other hand, he is headed for the job of skilled specialist, training continues for an additional year or two and includes such subjects as laying out work and setting up a machine tool.

Learners generally get higher wages than first-year apprentices. Veterans in learner jobs may qualify for monthly allowances from the Government.

Persons without previous machine shop experience may be hired directly as learners, or lower-grade machine shop workers may be upgraded to this work. Men whose lack of education or whose age disqualifies them for apprenticeship can often get into machine shop work through learner jobs, particularly those for semiskilled operators. The requirements for trainees in the skilled machine tool specialist's work often closely approach those for apprentices.

Trade or Vocational Schools

There are many trade schools, public and private, which offer a 1- or 2-year course in machine shop work. These courses cannot qualify men as machinists, tool and diemakers, or machine tool operators. However, many employers, in filling apprentice or trainee jobs, give preference to graduates of a good trade school. In some cases, those who have completed a trade school course may be allowed to go through apprenticeship or other on-the-job training in less than the usual time. Before enrolling in one of these schools, the prospective student should find out if the courses are considered satisfactory by employers and unions in his town and if the school is properly accredited. (See: How to Get More Information About Machine Shop Jobs, p. 25.)

Choosing a Machine Shop Occupation

As we have seen, a man who wants to get into machine shop work may be able to choose among several different routes into the field. Of course, there are a number of factors, such as individual aptitudes, which have to be taken into account in deciding what kind of job a person should seek. In addition, the availabilty of each type of work in a particular commmunity has to be considered. These problems cannot be solved here, but what can be done is to compare the various possibilities with respect to employment prospects, earnings, opportunities for promotion, and job security.

In many ways, the job of learning to be a semiskilled machine tool operator has the least to offer. For one thing, there are likely to be few openings for trainees during the next several years. Moreover, although the earnings of experienced operators are not far below those of more-skilled machine shop workers, their promotional opportunities are much more limited, and their chances of being among the first to be laid off when business is declining are greater. On the other hand, operators after a few months on the job generally earn more than first- or second-year apprentices. There is also the possibility, in some cases, of a man beginning as an operator and taking an apprenticeship at a later date. Finally, it should be remembered that, although there are disadvantages to this occupation compared with other machine shop jobs, the necessary investment of time and effort in learning the work is relatively small. Thus, a machine tool operator who left machine shops for another line of work would lose less than would a highly trained man.

Trainee jobs leading to the occupation of skilled machine tool specialist generally provide much better opportunities. There should be many openings, in the period immediately ahead, for inexperienced men to begin specialist training Trainees' earnings are often higher than those o apprentices and the learning period is shorter Experienced specialists often receive about as much pay as all-round machinists, and in some cases more. They have fairly good chances for promotion, although their opportunities are more limited than those of journeymen, and favorable prospects for continued employment in the future.

In general, a machinist or tool and die make apprenticeship is the most desirable course. As w have seen, getting equivalent training any othe way is difficult. It is true that apprentices' pa is relatively low at the start (except for veteran receiving allowances under the GI bill) and tha journeymen often earn no more than less-skille men. In the long run, however, those who complete an apprenticeship are likely to fare bette than other machine shop workers. For one thin a wider range of jobs is open to them. A journeyman machinist, for example, can not only work a an all-round machinist but can also qualify as set-up man or skilled operator on any standar machine tool. Because of this ability to do diffe ent kinds of work, journeymen have the be chances to get and to keep jobs. They also ca transfer more readily than less-skilled men fro one plant to another. Moreover, there is the fa that most supervisory jobs in machine shops a ed by promoting experienced journeymen. uring the next few years, there should be many enings for apprentices.

There is one other way of going into the machine op field which has not been previously consid- d here. This has to do with the opportunities engineering school graduates. Many employ- take on these college trained men, give them a r or two of experience in machine shop jobs, l then, if the men show promise, assign them to gineering, sales, or supervisory positions. It is ieved by many in the field that this combination engineering education and practical shop ex- rience gives a man the best chance to rise to an ecutive job in metalworking industry.

To sum up, it would seem that the best advice to oung man planning to go into machine shop rk is that he seek the highest level of skill which abilities permit and available openings allow.

ow To Get More Information About Machine Shop Jobs

There are many sources of information about chine shop jobs and training. Young men erested in apprenticeships or trainee openings y consult the nearest local office of their State ployment service. They may also write to or it the local headquarters of unions having chine shop workers among their members. Vet- ns may get information, especially about Gov- ment financial aid, at the nearest office of the terans' Administration or Veterans' Informa- n Center. Information about trade school rses can be obtained from local public school tems or the State superintendent of public in- uction. Questions regarding the standing of vate trade schools may also be sent to the Na- nal Council of Technical Schools, 839 Seven- nth Street NW., Washington 6, D. C., or to the erican Vocational Association, 1010 Vermont enue NW., Washington 5, D. C. The addresses nachine shops in one's community can be found he classified section of the local telephone book, under such headings as "machine shops," "die makers," "machinery," "railroad companies," and "automobile manufacturing companies."

Additional Bureau of Labor Statistics Information on Machine Shop Work

Employment and pay-rolls.—The Employment Statistics Division of the Bureau of Labor Statistics provides monthly estimates of employment, hours, earnings, and labor turn-over for each of a large number of individual industries, including the various metalworking industries which employ the bulk of machine shop workers. This information is published in the Monthly Labor Review[1] and in free mimeographed releases each month.

Occupational wage rates.—Detailed information on wage rates in machine shop occupations in many industries is contained in publications of the Bureau's Wage Analysis Branch. Also included are data on such related subjects as unionization, incentive pay, bonuses, and vacations. Recent studies include Wage Structure of the Machinery Industries, January 1945; Wage Structure of the Machine Tool Industry, January 1945; and Wage Structure of the Machine Tool Accessories Industry, January 1945. Mimeographed copies of these studies will be furnished free upon request.

For January 1945, there are also local summaries covering each city of 100,000 population or more. Information of this type for October 1946 or January 1947 will be available in the near future.

Industrial hazards.—Statistics on work injuries in each of a large number of industries, including many metalworking industries, are collected by the Bureau's Industrial Hazards Division and appear in the Monthly Labor Review and in free mimeographed releases.

[1] Metalworking industries included are iron and steel and their products; electrical machinery; machinery, except electrical; transportation equipment, except automobiles; automobiles; and nonferrous metals and their products.

[2] Sources: Published employment series of the Bureau of Labor Statistics were used for the period, 1929 to October 1946. Preliminary employment estimates for 1923 to 1928 were derived from unpublished Bureau data, and are not entirely comparable with the estimates for later years. The seri covering 1899 to 1921 are based on Employment in Manufacturing, 1899–193 by Solomon Fabricant (National Bureau of Economic Research, Inc., 1942 Fabricant's data were adjusted to the 1929 level of the Bureau of Lab Statistics series.

[3] Data are not available.

Occupational Outlook Publications of the Bureau of Labor Statistics

Studies of employment trends and opportunities in the various occupations and professions are made by the Occupational Outlook Service of the Bureau of Labor Statistics.

Reports are prepared for use in the vocational guidance of veterans, young people in schools, and others considering the choice of an occupation. Schools concerned with vocational training and employers and trade-unions interested in on-the-job training have also found the reports helpful in planning programs in line with prospective employment opportunities.

Occupational Outlook reports are issued as bulletins of the Bureau of Labor Statistics; sometimes they are also published in the Monthly Labor Review (subscription price per year $3.50; single copy, 30 cents). Both the Monthly Labor Review and the bulletins may be purchased from the Superintendent of Documents, Washington 25, D. C.

Two types of reports are issued:

Occupational Outlook Bulletins describe the long-run outlook for employment in each occupation and give information on earnings, working conditions, and the training required.

Special Bulletins are issued from time to time on such subjects as the general employment outlook, trends in the various States, and occupational mobility.

Nonprofit Housing Projects in the United States

Bulletin No. 896

For sale by the Superintendent of Documents, U. S. Government Printing Office
Washington 25, D. C. - Price 25 cents

Letter of Transmittal

UNITED STATES DEPARTMENT OF LABOR,
BUREAU OF LABOR STATISTICS,
Washington, D. C., March 20, 1947.

THE SECRETARY OF LABOR:

I have the honor to transmit herewith a report giving a detailed description of 20 housing projects in which self-help or cooperative methods were used. They are given here as a means of practical assistance to similar projects elsewhere.

The report was prepared by Florence E. Parker of the Bureau's Labor Economics Staff. The Bureau also wishes to acknowledge with thanks the cooperation of the many persons connected with the projects here described, who gave freely of their time and information.

EWAN CLAGUE,
Commissioner.

HON. L. B. SCHWELLENBACH,
Secretary of Labor.

Bulletin No. 896 of the
United States Bureau of Labor Statistics

Preface

The present report is a revision of an earlier one (now long out of
rint), with additional material on later developments and procedures.
The 20 nonprofit housing projects here described were selected as
epresentative of varying methods of sponsorship, of techniques of
nancing, or of other procedures, or because they illustrated mistakes
be avoided. The dwellings provided in these projects ranged
prewar prices) all the way from a $500 structure, 24 by 24 feet, with
modern conveniences except running water, through a modest
3,500 to $4,000 dwelling, to terrace apartments and housing costing
to $6,500.

In all except two cases each association has actually provided living
arters for its members. The exceptions were included because they
ere examples of (1) cooperative action under an urban redevelop-
ent law, and (2) unusual membership arrangements.

It is hoped that the presentation will be helpful to groups interested
the joint provision of housing on a nonprofit basis. The methods
ed in the projects which form the subject matter of this report are
aptable to other projects, but interested groups should consider them
om the point of view of their own needs and circumstances.
though some consideration is here given to methods of financing
d sources of funds, the treatment of these matters is by no means
mplete, and the reader is urged to study also the National Housing
gency's manual, entitled "Mutual Housing—A Veteran's Guide," ob-
nable from the Superintendent of Documents, Government Printing
fice, Washington 25 D. C., at 15 cents a copy. Other points to be
nsidered are possible unpaid taxes, liens, or special assessments
ainst the property, and building-code restrictions regulating the
pe and cost of buildings in the area considered.

Proper procedures in establishing a housing cooperative are set forth
U. S. Bureau of Labor Statistics Bulletin No. 858 (Organization and
nagement of Cooperative and Mutual Housing Association), obtain-
e from the Superintendent of Documents at 20 cents per copy. This

pamphlet covers considerations regarding selection of land, architect, building plans, and contractor, as well as the financing and operation of the completed project. Appendixes give model by-laws, sample share-subscription agreement, model lease, citations of cooperative and housing laws, etc.

The extent to which the cooperative approach is used is optional with the members; cooperation may begin and end at any point they choose. The members may combine for the purchase and/or division of the land only, after which each member carries on for himself. They may also furnish themselves community facilities, architectural service, and even title insurance. They may decide upon joint purchase of materials and contracting for construction, or joint action through the entire construction stage, hiring the work done or doing some or all of the work themselves either by the exchange of labor or by each member working on his own home. They may decide that, having cooperated at certain points, they will stop there, giving each member title to his dwelling and unrestricted control of it thenceforward.

In some cases cooperative activity may begin only after the completion of the project. The members who will occupy the dwellings may participate actively in every step from the very beginning in some projects, while in others they may benefit passively by the activities of the sponsoring organization, in which (up to the time of their taking occupancy) they had little voice.

Some hardy groups are willing to follow the cooperative method in all the steps up to and including that final test—joint permanent ownership of the project by the cooperative association. Others have started on that basis, but were defeated by inability to obtain financing or by the lack of thoroughgoing acceptance of the cooperative methoc by members who desired to own and control their domiciles individually.

In some cases cooperation is carried on informally, in others throug the medium of a regularly incorporated association which may b continued indefinitely or dissolved when its purpose has been served

It will be apparent, from this report, that housing is a complicate process which calls for much patience, good technical advice and assis ance, and competent management at all stages. Innumerable facto will call for a succession of decisions by the membership, upon th wisdom of which the success of the entire project may depend. A regards site, unimproved low-cost land may turn out to be very expe sive after the cost of installation of utilities is included. Means ar cost of transportation and convenient access to shopping facilities a other factors which should be considered. The probable cost of th completed dwellings should be predetermined with some accuracy, so that the prospective member may consider it in relation to his family income, resources, and prospects. Some stability of prices is essential here. In times, like the present, when prices are either rising rapidly or show indications of a sudden fall, the group should proceed cautiously or postpone action.

Above all, the housing association should not undertake too large a burden, especially at first, of luxury items or of community amenities (such as auditorium, gymnasium, swimming pool, stores, nursery, etc.), and so avoid getting in over its head. If space is left, these can be provided at a later time when resources are available and the association has proved itself financially. Many a group has eventually lost its equity by undertaking more than its members had the financial ability to carry through.

Nonprofit Housing Projects in the United States

Chapter I.—Introduction

Until comparatively recently, cooperative housing in the United States was limited almost entirely to apartment houses which had been built or purchased by cooperative associations. During the few years preceding World War II, several cooperative developments providing single-family dwellings were launched, and many more are now being planned; some of the latter have acquired land, but few (except those of veterans) have been able to secure the necessary authorizations to enable them to start construction. A recent development has been the formation of mutual home-ownership associations to purchase and operate housing built by the Federal Government for war workers but designated for mutual ownership at time of construction. In other cases veterans' cooperatives have bid in projects put up for sale by the Federal Public Housing Authority.

Together, these projects form a significant development in the field of low-cost nonprofit housing. The present report describes 20 of these, selected as illustrative of procedures which are applicable to other projects or of mistakes to be avoided. Four projects illustrate all-the-way cooperative housing, the cooperative being responsible for all the steps through completion of the dwellings, and retaining permanent title to the property. In two, the association had no hand in the preliminaries or in construction, but took over a finished project. Self-help was the significant feature in four, with the members doing a considerable part of the construction labor themselves and receiving title to their properties on completion of the project or of payment. The others involve the development of a new community, complete with streets and public utilities; varying degrees of participation by labor organizations; a building-guild experiment to provide annual earnings to building-trades workers as well as houses for the members; and certain rather uncommon financing methods.

It is believed that the value of the report lies in its detailed description of varying procedures and techniques—all capable of use in other projects.

Sponsorship of Projects

The projects described were carried on under various types of sponsorship. Four were sponsored by one or more labor organizations. In one case the sponsor was a clothing-trade union, in two a textile union, and in the fourth the unions belonging to the city building-trades council. In three cases, some union funds were used for varying periods; in the fourth, the labor organization advanced no money, but it did act as sponsor and guarantor of the building project.

Cooperative associations without any outside sponsorship carried through five of the projects, and the same procedure is expected in a sixth. In other projects a university employees' association, a city housing commission, a religious service organization, a private citizen, a United States Senator, and a foundation acted as sponsors.

Membership Considerations

Housing associations have sometimes been criticised on the ground that they usually have restrictions on membership. A few associations have admitted only members of the sponsoring group. Generally, however, at the start membership is open to all persons interested in providing themselves with dwellings on a nonprofit basis. It is closed only after the project is finished and the dwellings are occupied; thereafter membership is limited to the member-owners. This is done for practical reasons. The activities of most associations have been limited to one project. Once this is completed, the chief function thereafter is the management of the project and possibly of collateral cooperative activities (store, tea room, nursery, etc.). Nonresidents are not generally interested in becoming members of an association which provides them no benefits and, even if they were, the residents probably would not welcome nonresident participation in running their community.

An arrangement, whereby resident control of dwellings as well as open membership in the cooperative is assured, has been worked out in one project. There any person interested in cooperative housing may join the parent association, which is a sponsoring and development organization. In each project developed by it, the residents are members of a separate community organization through which they operate and control the property, at the same time retaining their membership in the parent association.

Financing

Several of the projects illustrate financial participation by public authorities at Federal, city, and county levels.

One was the first building project of the Federal Public Works Administration after its establishment in 1934: this was a self-liquidating arrangement.

In the mutual home-ownership projects all the steps of land acquisition, community lay-out, and construction were carried out by the

Federal Government, using funds provided by Congressional appropriations. The cooperatives entered the picture only at the end of World War II, when the Government began to dispose of war housing. No subsidy was involved, as "economic" rentals were paid by the residents during Federal operation, and the property was purchased by the cooperatives at sums fixed by appraisers as representing its current value.

A different type of Federal financing was represented in one project. In that case the remainder of Federal funds that had been provided under the various relief acts, for the assistance of self-help activities carried on by the unemployed during the depression, were turned over to a State agency. The housing loans, made by the State agency from this money to the cooperative members, were also self-liquidating. Although self-help projects of various kinds were carried on in many States, with grants from Federal, State, and sometimes county and municipal funds, this project is the only one to the Bureau's knowledge in which loans were made for housing.

City assistance in various forms is involved in one case, in which apartments are being constructed under the New York State Redevelopment Companies Act.[1] For the purpose of encouraging slum clearance and the construction of good, low-cost housing, the act offers organizations which meet its requirements (rentals not to exceed specified amounts and limited return on investment) the advantages of land prices reduced through condemnation and the exemption of all improvements from taxes for a period of 25 years. In this particular project the city will also assist by widening adjoining streets and by improving and enlarging two neighborhood playgrounds and a nearby public school.

The one instance of city and county participation in the financing of housing in this country, which has come to the attention of the Bureau, was a project carried on some 20 years ago. Under a State law which is still on the statute books, city and county authorities invested funds under their control in the preferred stock of the housing enterprise. No element of public subsidy was involved, however, for nterest was paid on the stock, which was retired as the tenant-owners paid for common stock to replace it. This method of financing housng has been rather common in Europe.

Nonprofit Aspects

Practically all of the projects here described were on a nonprofit basis. Leaders and sponsors contributed their time at all stages. Some architects reduced their charges in consideration of the size of the job, others because they were in sympathy with the aims in view. Contractors worked either on a flat fee or a percentage and some on a profit-sharing arrangement. Materials, equipment, and even furniture were bought at substantial savings.

---

[1] Similar legislation has been enacted in some 20 States.

Much work was done by the members themselves. Clearing and grading the land, cutting the streets, excavating for basement and septic tank, pouring concrete, making building blocks, quarrying and shaping building stone, laying subfloors, making interior trim, other inside carpentry, laying the sheathing for the roof, interior and exterior painting—these were some of the processes done by the members.

As the occupants of the dwellings benefited from all of these factors in terms of both money and quality of materials and workmanship, it would be expected that they would take steps to insure the continuance of the nonprofit feature.

In associations adhering strictly to cooperative principle the member is given not a title to an individual dwelling but stock in the association or a certificate of indebtedness. A withdrawing member turns his stock back to the association either at par or an amount arrived at by appraisal which takes into consideration depreciation and current market conditions. This central-ownership arrangement has the disadvantage that no member can dissociate himself from the project unless he is prepared to withdraw from membership altogether. All sink or swim together and, unless a sufficient prepayment or reserve has been built up, this may be fatal in times of depression when a large proportion of the members are unable to meet their payments. Under good, far-sighted management, however, the central-ownership arrangement has the advantage that the cooperative community is preserved, group control prevents neighborhood deterioration, and no member can cash in on the previously donated work of others or on unusual market conditions—a situation almost impossible to control if fee-simple title is granted, as has been amply demonstrated in the experience of the projects here covered.

In a majority of the projects the agreement between the housing association and the member carried a limitation on the member's right to dispose of the dwelling occupied by him. In most instances a member desiring to withdraw and dispose of his holdings was required to give the association an opportunity to redeem his equity. If it failed to do so within a specified time, he was at liberty to transfer it to a purchaser acceptable to the association.

In some cases the provision was a dead letter, because the association had no funds with which to redeem the member's equity. In others, the association had given the member fee-simple title to his dwelling and could not enforce the withdrawal provisions.

The war years of extreme labor mobility, high prices, and scarcity of housing put a severe strain on the members' acceptance of the nonprofit principle. Often the temptation to profit by selling out at high prices proved to be more than they could withstand. Thus, in St. Paul, according to a late report, giving of title "left the door wide open for speculation." Some houses were sold three or four times, each time at a higher figure. The cooperative spirit in which the homes were undertaken disappeared. The housing association is still (December 1946) in existence, but is dormant, and the former president states that it plans no further construction. Other cooperative activities which were tried could not thrive in this atmosphere and also died of inanition.

In Penn-Craft (Pa.), although it was expected that the isolation of the community would limit the sale of properties at high levels, experience demonstrated the advisability of restrictions. Some restrictions were therefore incorporated in the lease, requiring approval by the association of any sales. In Watsonville (Calif.), by 1946 there had been almost complete turn-over of occupancy—the process having been hastened by the original residents' fear of possible bombardment by Japanese submarines (Watsonville is a coastal town) and by wartime employment opportunities elsewhere. At Front Royal (Va.), almost before the houses were completed one dwelling had been sold by a member, at a $2,000 profit. Among the described associations in which individual title rests with the member, Crestwood (Wis.) appears to have been most successful in retaining its original group intact. Several houses had been sold but none, it is said, at disproportionate prices; those houses the asking prices for which were regarded as exorbitant remained unsold as a result of adverse community opinion.

As would be expected, projects of the apartment-house or multifamily type have made most use of the lease-stock arrangement because of the difficulty of giving title to a single apartment or dwelling unit. During the depression, most of the genuine apartment-house cooperatives (including many not described here) weathered the storm successfully. Others, however, lost their buildings through foreclosure and in still others, which either had no restrictive provisions or did not enforce them, there was a considerable turn-over of membership through transfer of shares. The lease arrangement is a feature of the mutual plans at Dayton (Ohio) and South Bend (Ind.), which are both of such recent origin as to make appraisal of ultimate success impossible. The Amalgamated group, with an experience covering some 20 years, has been outstanding in its financing, management, and preservation of cooperative principle and spirit.

Member's Financial Interest

In the Amalgamated buildings, where the cost averaged about $1,500 per room, the member had to make a down payment of $500 per room. In the East River Cooperative Apartments, the member's required equity is also $500 per room, or about 20 percent; and in Group Housing Cooperative, it is expected to be 15 to 20 percent. In most of the projects here described, however, each member was required to have an initial equity amounting to about 10 percent. This is the minimum proportion required for FHA insurance (utilized in at least five of the projects). The same requirement was imposed at Front Royal, as well as in the Milwaukee project (which long antedated FHA insurance). One leader believes that 10 percent is the very minimum for safety and for insuring sufficient member interest in making the project a going concern. Some confirmation of his opinion is found in the experience of the United Workers' project (New York City) and in other associations not here described. From United Workers members, only $250 per room was required—$125 at time of joining and $125 within a year. This underfinanced association was never able to meet its obligations and the project was finally taken over by the creditors.

In the Wagner-Ellender-Taft housing bill, which was considered in the 79th Congress but failed to pass, mortgage insurance on 95-percent loans was proposed for mutual-ownership projects, with the members providing only 5 percent of the total cost. For housing built under the Lanham Act and designated for mutual home ownership, no down payment of any kind was required. However, under the latter plan, the amortization amounts included in the rents paid during the 2-year probational period were credited as down payment when the contract of purchase was entered into at the end of that period. In a sense, therefore, although no cash payment is required of the member, when the home-ownership corporation takes over the property from the Federal Government he has already (through his monthly rental) made some payment on principal. Some observers, however, question whether this is a sufficient investment to make him work very hard for the survival of the project as a cooperative.

Protective Measures for Association and Members

One of the best protections is the building up of mortgage prepayments. Such prepayments provide a cushion against disasters. This has been done by several of the associations here described. The mutual housing associations have an arrangement under which the individual members pay off their indebtedness at a faster rate than the association itself, thus building up reserves in the treasury of the latter which can be drawn upon when needed. In one self-help project the agreement between member and association relates the monthly payments to the family income. In prosperous times the family pays its loan as fast as it can; in hard times, when income falls, its payments (subject to a prescribed minimum) may be sharply reduced.

Various types of insurance—formal and informal—have been used also, to protect the participating families and incidentally the whole project. In one case, group insurance was obtained, covering the obligations of families whose breadwinner died or was totally disabled before completing payment. Another had a "widows' insurance"—an informal plan under which each member made a yearly contribution proportioned to his unpaid obligation. In a third case, all the members voluntarily contributed to a fund from which to pay all or part of the monthly payments of families in distress or of drafted men.

Cooperative Accomplishments

Among the accomplishments of cooperative action in the projects here described were the following, each of which resulted in substantial savings for the membership:

1. Land acquisition, provision of public utilities, and complete community planning.
2. Integrated architectural and contractual services. In this way 2 percent on construction was saved in two cases, 1 percent in another.
3. Title insurance, and use of a master title to land.
4. Bulk purchase of materials and furniture and/or equipment. On the former, savings were estimated at about $200 per house in one case; on the latter, two associations saved 25 percent.
5. House construction on contract or by exchange of labor. This saving cannot be evaluated, but is known to be great.
6. Permanent operation and maintenance of some or all of the property. Mutual-ownership projects are notable for their economy of operation.
7. Tax savings, made possible by group operation under urban redevelopments acts or under limited-dividend statutes, resulting in a saving of $30,000 per year in one case.
8. Interest savings by collective bargaining, resulting in savings of $97,865 in one case, $900 per year in another. and over $2,700 per year in a third.

In one case, it was estimated that savings on land, wholesale purchase of materials. effective use of labor, and elimination of speculative profit saved as much as $1,500 per house.

Present Cooperative Sources of Assistance

TECHNICAL ASSISTANCE

The National Cooperative-Mutual Housing Association was formed on the authorization of a conference of local housing associations, held in May 1946. It was represented at the Congress of the Cooperative League, in September 1946.

Although the association is still in its infancy, its plans cover a wide range of activities, including the provision of technical service, accounting, the training of project managers, etc. Structurally, it will probably be a federation of regional associations, which will in turn be composed of State federations of local associations.

Already one regional organization has been formed: the North Central States Housing Association, organized in November 1946. It plans to provide assistance on "legal questions, site planning, promotion, and education," in its territory—Indiana, Michigan, and Minnesota. The consensus of the meeting that established the organization was that purchases of building materials should be made through regional cooperative wholesales wherever possible; also that housing associations should help to finance the production of such materials by National Cooperatives (the national commodity organization).

Very few of the cooperative wholesales offer technical advice or assistance. Among these few are Eastern Cooperative Wholesale, which has a full-time housing adviser who is himself an architect; Associated Cooperatives of California which provides advice on organization procedure, legal questions, and land surveys; Midland Cooperative Wholesale which offers assistance in organizing; and Consumers Cooperative Association which provides building plans and specifications, advice on building materials, and legal assistance.

It is evident from the above that the distributive cooperative movement has hardly made a beginning in this much-needed service. However, with the development of the central housing federations, it is probable that most of the technical assistance will be provided by the latter.

BUILDING SUPPLIES

The Cooperative Congress in September 1946 by resolution urged National Cooperatives to establish "a strong division for the procurement of housing materials and supplies." The latter organization has for some years handled galvanized and asphalt roofing, cedar shingles, and nails. Since the 1946 Congress, it has been exploring the possibilities of prefabricated houses, millwork, steel shafts, wall board, bathroom tile, and numerous other items. The expansion and coordination of existing productive facilities is also being considered, as is likewise the purchase or lease of lumbering facilities in the West, in order to help supply the member regionals.

Paint, shingles, and lumber are produced by some of its members (regional wholesales), either in their own factories or in those owned jointly with other cooperatives. Thus, the International Cooperative Lumbering Association, the members of which are seven regional wholesales in the United States and four in Canada, produces red-cedar shingles. Indiana Farm Bureau Cooperative Association owns six sawmills and Consumers Cooperative Association (Missouri) owns one.

On the West Coast, Associated Cooperatives of California opened a building-supply department January 1, 1947. The association has made a loan to a small lumber mill, in return for the purchase rights to all its output. One housing association in its territory had already joined the wholesale by the end of 1946, and others had indicated their intention of doing so.

In Indiana the 60 county cooperatives which are members of the Indiana Farm Bureau Cooperative Association (the wholesale) all have lumber yards, the supplies for which come from the wholesale association. Most of them also offer a roof-applicating service and spray-painting service. The wholesale itself, as noted, owns six sawmills, is part owner of the red-cedar shingle mill of the International Cooperative Lumbering Association, and is helping to finance other lumber acquisitions in the West. In addition to lumber, it handles steel, and (in cooperation with Purdue University) is promoting a homestead-improvement program.

Central Cooperative Wholesale carries a complete line of building materials; and many such supplies may also be obtained through Eastern Cooperative Wholesale. (For a list of supplies and technical services available through the cooperative wholesales, see Appendix B, page 85.)

In addition, there are possibly 100 farmers' cooperative lumber yards and hundreds of other retail coöperatives throughout the country which handle lumber and certain other building materials and supplies as part of a general retail business.

Possible Avenues of Further Development

SOURCES OF FUNDS

The experience of the projects here described suggests several possible sources of financing which might be developed. Union funds form one such source. No individual labor organization would wish to tie up any considerable amount of its resources in housing. However, in the aggregate, the money controlled by unions in this country is considerable. One leader in cooperative housing, who is also a man of union background and experience, suggests that diversion to housing of even as little as 5 percent of each organization's funds would be of inestimable help. A central agency, formed for the purpose on a local or State basis, could use the money so raised as a revolving fund from which to make construction loans and loans for member equity. This would give the initial shove for projects that might otherwise never be able to get started. The agency could be formed as a regular corporation, or preferably as a cooperative, with the contributing organizations as members which would hold stock in the amount of their contributions. This procedure has already been used in Tulsa, Okla., where a small building project was financed through a corporation in which members of the city building-trades council took part.

Members of regional cooperative wholesale associations might also vote to invest some of their patronage refunds from the central organizations in this central agency or in a similar fund. With the increasing collaboration between labor organizations and cooperatives, such a joint enterprise could easily be worked out.

The National Cooperative Finance Association was formed in 1943 to coordinate the resources of the consumers' cooperative movement and to assist in financing cooperative enterprises. Its membership consists of eight regional wholesales and National Cooperatives. The finance association was urged by the 1946 Cooperative Congress to "organize immediately a program which will make mortgage credit available to cooperative and mutual housing associations." There are some possibilities in this direction.

Credit unions are another potential source of financial assistance for housing. In a number of States these associations are permitted to make loans on the security of real estate; the same is true of associations organized under the Federal Credit Union Act, but the period of such loans is limited to 2 years. In States where this is not permissible, loans might be made on the basis of other security. Also, some of the laws authorize the making of loans, secured only by the signature and good faith of the borrower, up to $100 and even in some States $300. Although these are small amounts, they would be helpful in cases where only a simple dwelling is concerned and much if not most of the work is done by the family, on a self-help basis. In other cases, such amounts could be used toward the member's down payment.

The Metropolitan Life Insurance Co. has made numerous loans for housing purposes, the Mutual Life Insurance Co. made one to an association herein described, and probably many other similar organizations have also done this. Among cooperative insurance companies, at least one group—the five companies operating under a unified system in Wisconsin and Minnesota—makes loans, to members of cooperative associations, for housing. Where the insurance laws permit, this would seem to be another good use for accumulated insurance assets.

Building and loan associations, savings banks, and GI loans are obvious sources. The last-named undoubtedly will be utilized more effectively when regulations are worked out whereby the Veterans Administration guaranty can be applied to a cooperative project as well as to dwellings individually financed. If legislation along the lines proposed in the Wagner-Ellender-Taft bill is enacted, 95-percent mortgage insurance would be available to cooperative and mutual housing projects, thus facilitating the obtaining of funds from the regular lending agencies.

PROVISION OF TECHNICAL SERVICE

Undoubtedly, one of the major needs of the new housing groups—and one that most of them lack—is that of competence in the technical matters of law (incorporating the association, searching titles, drawing up and closing the land-purchase and building-construction contracts, etc.); selection of qualified architects and contractors, as well as accounting and possibly engineering service.

Such specialized knowledge should be available to cooperatives throughout the country. It could be furnished as part of the consumers' cooperative movement, through State, regional, or the national federations, or could be supplied through an independent association of professional technicians operating as a workers' productive association. It has been suggested that a national association of technicians (experts in accounting, finance, law, architecture, etc.) be established, with branches in various parts of the country. Such an organization could enroll in its membership socially minded persons in the above professions—all available at designated local establishments.

An organization of the latter type, but on a local scale, was actually incorporated in Washington, D. C., just before the beginning of the war. This "housing producers' cooperative" was started with the idea of enlisting the services of local professionals who would furnish services in all the various lines needed in building a house. This association never went into operation, as the war stopped private building. Similar organizations are feasible, however, and might be formed where the appropriate professions are or can be interested in the idea.

To get such a service into actual operation, however, presupposes some organizing drive and a source from which such a drive can emanate. For this reason, if technical service is to be made available on either a local or national basis, it is more likely that the motivating force will come from the consumers' cooperative movement rather than from the professions themselves.

If this is true, then undoubtedly the cooperatives would prefer that such service be provided as one arm of the consumers' movement rather than as a producer function.

Ultimately, it seems probable that this service will be furnished by cooperative associations in the housing field. In that case, as is usual in the consumers' cooperative movement, initiative will come from the local housing associations, which can (and have the duty to) make available for the benefit of new groups what they themselves had to learn by trial and error. This they can do by organizing on a State, regional, and national basis and establishing in these federations departments charged with providing technical assistance.

At present the available machinery consists of a national association (just getting under way) at the top and local associations at the bottom. Except for one regional association (also new) there is as yet no intermediate organization. Reports indicate, however, that with housing groups springing up all over the United States, federation should not be too far in the future.

Chapter II.—All-the-Way Cooperative Housing

Amalgamated Housing Projects, New York City

The Amalgamated Clothing Workers of America was the first of the labor unions to take an active interest in providing better housing for wage earners at lower rentals through the cooperative method. At the very beginning, however, the sponsors of this activity realized that a housing project should not be confined to members of one industry or one labor organization.

The cooperative housing idea was first broached at the 1924 convention of the union, but no definite action was taken until April of the following year. Prior to the convention members of the union, who were also active in the organization's credit union, formed the A. C. W. Corporation [1] to provide themselves with housing on a cooperative basis. This corporation was later taken over by the Amalgamated Clothing Workers and acted as its construction company. The first project was begun largely to demonstrate that low-rental housing is possible if carried out on a large scale.

In all, seven separate building projects were undertaken—three by the Amalgamated Housing Corporation, two by the A. H. Consumers Society, Inc., one by Amalgamated Dwellings, Inc., and one by East River Cooperative Apartments, Inc.

The size and year of completion of each of the projects are shown below:

	Apartments	*Rooms*
Amalgamated Housing Corporation, Bronx:		
1926–27	303	1, 187
1929	192	822
1931–32	115	426
Amalgamated Dwellings, Inc., Manhattan:		
1930	236	930
A. H. Consumers Society, Inc., Bronx:		
1941	48	128
1946–47 [1]	30	108
East River Cooperative Apartments, Inc., Manhattan:		
1947–48 [2]	796	3, 047
Total	1, 720	6, 648

[1] As of December 31, 1946, this project was under construction; it is limited to veterans of World War II.

[2] As of December 31, 1946, this project had advanced to the stage of receiving bids for the construction.

The discussion in this section relates only to the first six of these projects. The seventh (East River Cooperative Apartments) is described on page 19.

---

[1] This corporation has since been dissolved.

For none of the above construction were union funds used. At the beginning, however, the union acted as sponsor and guarantor, and several organizations composed of union members or affiliated with the union (the New York and Chicago Amalgamated Banks, the Amalgamated Center, and the Amalgamated Clothing Workers' Credit Union) advanced temporary loans, to enable the project to get under way. Because of the success of the first venture, the later projects were able to obtain financing from regular agencies. However, as the later buildings were carried on largely for and by the same union group, and notably under the same leadership,[2] the name Amalgamated was used for all.

LOCATION AND DESCRIPTION OF BUILDINGS

The buildings of Amalgamated Housing Corporation and those of A. H. Consumers Society, Inc., occupy a triangular plot in one of the finest locations in the Bronx. On the north side this development is bounded by Van Cortlandt Park, the city's largest public park, consisting of some 1,100 acres; on the east, by Mosholu Parkway; and on the south, by Jerome Park Reservoir. Families living in these apartments, therefore, have views of the park, the waters of the city reservoir, or the palisades of the Hudson. The proximity of the parks means access to the tennis courts, ice skating, and other outdoor recreation and exercise made available by the park facilities. The buildings are within 5 minutes' walk from two subways.

The first buildings erected by the Amalgamated Housing Corporation are of the walk-up type,[3] five stories in height. The buildings erected in 1929-31 are six and seven stories in height, and provide elevator service. Those of the A. H. Consumers Society are two and three stories high. Privacy is assured by the installation of many stairways; in the walk-up buildings, only two or three apartments open onto a single staircase and in the elevator buildings, only three or four.

The buildings cover approximately half of the plot, the other half being used for gardens and landscaped areas. The structures are in the form of hollow rectangles. Those erected prior to 1941 are of Holland brick, of mixed colors; the succeeding ones are of domestic red brick. All buildings are equipped with incinerators, mechanical refrigeration, gas ranges, bathtubs and showers, as well as hardwood floors. (For view of interior court of Bronx buildings, see cover.)

The downtown building, erected by Amalgamated Dwellings, Inc., occupies a square block, 300 x 200 feet, and is bounded by Grand,

---

[2] A. E. Kazan, the prime mover in all the projects, and their manager after completion, is also the leader in the East River Cooperative Apartments.

[3] Elevators were eliminated under a compromise reached on a restriction in the deed which had prohibited the erection of an apartment house on the site.

Sheriff, Broome, and Columbia Streets. This is one of the most neglected regions in the city of New York; in about a third of the area the buildings have been either demolished or boarded up, and the other two-thirds are occupied by industrial buildings or tenement houses. At one time this was one of the most congested districts in the city.

The Amalgamated structure is six and seven stories in height, and contains 236 apartments, ranging from two to five rooms. It is equipped with 8 automatic elevators, incinerators, mechanical refrigeration, showers, and bathtubs. The lay-out of the apartments and the design of the buildings is similar to those in the Bronx, the same architect having been employed in both. The high cost of land made it necessary to use a greater percentage of the plot for the building—60 percent. A landscaped court of 24,000 square feet provides a pleasant outlook to most of the apartments.

This building—which is in sharp contrast to its surroundings—demonstrates the possibilities of cooperative effort in replacing dilapidated buildings, in substandard areas, by good housing.

LEGAL STATUS AND FINANCING

Amalgamated Housing Corporation and Amalgamated Dwellings, Inc., are limited-dividend companies organized under the New York State Housing Act. A. H. Consumers Society, Inc., is organized under the regular corporation law.

The buildings erected by the first two of these organizations enjoy a 20-year tax exemption (on buildings, not land). In return, their rental charge is limited to $11.00 per room in the Bronx and $12.50 in Manhattan. The consequent savings are therefore considerable. Under the original law, the granting of tax exemption by the municipality was mandatory, if the project was approved by the New York State Board of Housing. The law was subsequently amended, making city approval optional. As this provision to some extent nullified the benefits of the act, in that it limited rentals without assuring tax exemption, the buildings erected in 1941 and 1946, although sponsored by the same group as before, were undertaken as an enterprise of the A. H. Consumers Society which is not under the housing law.

The first six buildings cost nearly $1,970,000, of which $315,000 was for land and $1,654,359 for construction. Construction cost averaged $1,437 per room and 38.95 cents per cubic foot (including basement space). A 20-year 5-percent first mortgage of $1,200,000 was obtained from the Metropolitan Life Insurance Co. The remainder came from payments by the tenant-members, at the rate of $500 per room, and from the sale of 6-percent preferred stock to tenants, the union, and other friendly organizations. In addition to the tax exemption (saving nearly $30,000 a year, or $2.11 per room per month), savings were made in other ways—by the purchase of comparatively low-cost land, by the ½-percent reduction in interest on the Metropolitan mortgage (lowering the rate from the customary 5½ to 5 percent saved the housing association an estimated $97,865), and from the waiver of the usual recording fees, revenue stamps, etc., by the authorities and the insurance company.

Building 7 in the Bronx had a construction cost of $1,003,021; this was at the rate of $1,322 per room and 41.79 cents per cubic foot (including basement).

The last unit erected in the Bronx by the Amalgamated Housing Corporation was considerably smaller than its predecessors and contained only 115 apartments. The total cost was about $570,000, of which $380,000 was obtained on a 5-percent first mortgage from the Metropolitan Life Insurance Co., and the remainder from the members.

The success of the Bronx projects prompted Aaron Rabinowitz, then a member of the New York State Board of Housing, and Herbert H. Lehman, then Lieutenant Governor (later Governor) of New York, to undertake the financial responsibility for the downtown Amalgamated venture. During the construction period they advanced about $800,000. The actual work, however, was carried out by the same group that built the Bronx buildings. The downtown building cost, for construction, $1,064,713—$1,272 per room and 38.03 cents per cubic foot. The expenditure for land, however, was considerably higher proportionately, bringing the total cost of the project to nearly $1,520,000. It was financed by a mortgage loan of $960,000 from the Bowery Savings Bank, $60,100 from the sale of debenture bonds, and the rest from members' down payments.

Although all the housing projects erected up to 1946 received mortgage loans from either an insurance company or a savings bank, a deviation was introduced in the construction of the 1946–47 unit of the A. H. Consumers Society. In order to reduce the interest rate, and thus keep rentals down, the cooperators living in the earlier buildings were urged to subscribe to mortgage-bond certficates, bearing 3 percent interest for the first 5 years and 4 percent for the second 5 years. The corporation will have the right to call in some of these bonds every year, or buy the entire amount, at will. Purchasers of these bonds will thus receive a fair return on their investment, and the whole operation will be a demonstration of the effectiveness of self-help cooperative effort.

Subscribers for apartments in this building are limited to veterans of World War II, with special preference for those who lived in other Amalgamated dwellings before joining the armed forces. As in all the other projects, they will subscribe for $500 in stock for each room.

receiving in return stock or a certificate of indebtedness and a lease to an apartment. The lease runs for 2 or 2½ years, with the option of renewal. The corporation, however, reserves the right not to renew the lease if the applicant is found to be undesirable. (Nearly 70 percent of the original tenant-cooperators in all the Amalgamated buildings still live in the projects.)

COST AND CONDITIONS OF MEMBERSHIP

In the admission of housing-association members, the members of labor organizations are given preference, but during the nearly 20-year period of operation many persons have changed their occupation, and a good many nonunionists are now living in the development. In general, preference is given to wage earners, members of labor unions, salaried people, and those who can be classified as belonging to the moderate-income group. The needle trades, with the Amalgamated Workers members comprising the largest single group, account for about 50 percent of the residents of the Bronx apartments and about 25 percent in the downtown building.

In the Bronx buildings, the applicant for an apartment was required to raise at least 50 percent of the investment; the rest could be met by contracting a loan. In order to enable the applicant to pay this loan over a long period, the assistance of the Jewish Daily Forward (a labor newspaper in New York City) was obtained. It arranged with the Amalgamated Bank for the latter to make loans to prospective applicants accepted by the housing corporation, permitting them to repay these loans over a period of 10 years and using as collateral a deposit of $150.000 made by the Forward. That deposit was gradually released as the loans were repaid.

In the case of the Amalgamated Dwellings, Inc., Messrs. Lehman and Rabinowitz pledged $350,000 [4] and authorized the bank to extend loans up to 70 percent of the required equity investment of the applicant. On the A. H. Consumers Society's 1941 building, the corporation accepted payment from the prospective member partly in notes to be paid in the course of several years and partly in cash. These notes were not discounted, as the corporation itself was able to carry the project.

The average rental in the buildings of the Amalgamated Housing Corporation project (Bronx) is below $11.00 per room per month; in that of the Amalgamated Dwellings (Manhattan) it is $12.22; and in the buildings of A. H. Consumers Society erected in 1941 (Bronx) it is $13.00. In the latter association's 1946–47 Bronx building the monthly charge is $16.00, this higher figure being necessitated by the high cost of construction and the fact that no tax relief is granted.

---

[4] This was in addition to the funds supplied by them during the construction period.

Two factors tending to retard the growth of cooperative housing are inability on the part of a good many applicants to raise the equity investment, and the uncertainty of being able to recapture the equity investment if at any time the applicant wishes to withdraw from the cooperative housing project.

In the Amalgamated, the redemption problem has been handled very successfully thus far, notwithstanding that the first buildings were built in a period of high prices and were subjected almost immediately to an unprecedented period of depression. Reserves for redemption of shares have been built up through the voluntary contributions by the residents, over a number of years, of half of their patronage refunds from A. H. Consumers Society and the housing corporation. In the spring of 1946 these reserves totaled some $250,000 in the Bronx and $65,000 in the downtown project, and the A. H. Co-op Community News could report (issue of October 1946) that no persons had left the community who had not "received a full refund of their equity." Distribution of refunds on the 1944–45 operations of the two Bronx associations (housing and service)—exceeding $50,000—was then in process. Members were being urged to continue their previous contributions to reserves, because "no one can foretell what the future will bring."

COMMUNITY AND COOPERATIVE ACTIVITIES

As the Amalgamated residents are a fairly homogeneous group and by themselves form a good-sized community, they have developed a community spirit and carry on many activities together. Among these, cultural activities form a considerable part. In the Bronx they include Sunday afternoon forums on topics of current interest, folk dancing, classes in current events, consumers' cooperation, drama, book-review group, dancing (children), nutrition, etc. For the children there are also a nursery school, supervised game-room activities, and an all-day Saturday recreation program under the direction of seven counselors.

During the war the Amalgamated members raised funds from which were paid half of the rents of resident fathers who were drafted, in order to insure that their families would be able to keep their apartments.

Both the Bronx and Manhattan projects carry on business activities other than housing. These activities in the Bronx are conducted by the A. H. Consumers Society, Inc., and downtown, by the Amalgamated Dwellings Cooperative Service, Inc., the stockholders in both of these being identical with the stockholders of the housing corporation.

The A. H. Consumers Society, originally formed as a service organization, is gradually taking on more and more functions. At present this corporation distributes milk and electricity cooperatively, runs a laundry service, and operates a food store in the development. It assumed the function of purchasing the stock of outgoing members of the Amalgamated Housing Corporation in cases in which there are no new applicants to take the place of those who wish to withdraw. It extends loans to prospective new applicants when they are unable to raise the required investment, and has also assumed the responsibility of erecting any additional buildings.

The net earnings of this corporation for the years 1944–46 were $20.545, $18,906, and $24.560, respectively. These earnings were distributed to the members in proportion to their patronage.

Recently this corporation also acquired the greater part of the vacant land in the immediate vicinity of the Bronx Amalgamated project, with a view to erecting additional cooperative apartments. It also acquired 16,000 square feet of business property on which it intends to operate a cooperative retail shopping center for the benefit of the community.

East River Cooperative Apartments, New York City

Thus far, to the Bureau's knowledge, only one cooperative project has been undertaken under an urban redevelopment law. It is the East River Cooperative Apartments.

Some 20 States have passed urban redevelopment laws, the purpose of which is to facilitate slum clearance and the reclaiming of blighted areas. Such processes, of course, imply large-scale operation and great amounts of money. Probably very few cooperative groups, by themselves, would be financially or technically qualified to provide housing under the redevelopment plan. If, however, they could enlist the interest of existing cooperatives, and of one or more limited-dividend, philanthropic, public, or mutual housing enterprises, such a project might be feasible.

Such agencies have in most cases a surplus of applicants for housing, who could be referred to the housing cooperative, as well as the necessary business and administrative experience.

Also, the urban redevelopment laws generally provide a method for land acquisition, through condemnation procedure if necessary; some of these laws likewise permit reduction of land charges to a level consistent with its use for dwellings or apartment houses.[5]

---

[5] The market price of blighted property is ordinarily so much greater than a reasonable use value that an urban redevelopment project would start with an impossible debt burden unless a large part of the deflation loss were met from public funds.

Tax exemption on the increased value of the redeveloped area, for a fixed period of years, is also provided in some statutes.

The East River Cooperative Apartments will embrace eight city blocks, an area of approximately 522,500 square feet; included in this area are a playground at the extreme northwest corner, Public School 110 at the extreme northeast corner, as well as the building of Amalgamated Dwellings, Inc., a cooperative housing project built in 1930 (see p. 14). The new enterprise is undertaken by a group of sponsors representing subscribers to the apartments, the City of New York, and the financial agency supplying 80 percent of the required funds as a mortgage loan.

This is an area in which property values have been declining for years. Vladeck Houses—a city-sponsored low-rent housing project—are situated nearby. Except for this city slum-clearance project and the Amalgamated building, no new housing has been undertaken in this district for many years.

METHOD OF PROCEDURE

The sponsors undertook to raise 20 percent of the cost of the project by the sale of stock or debenture bonds to the applicants for housing in the new enterprise. If necessary, the sponsors may attempt to obtain additional funds from other individuals and agencies that might be willing to assist in financing the development. The individual prospective cooperator is required to subscribe to $500 of stock or debentures for each room for which he applies; of this amount, $100 per room is paid at the time his application is filed and accepted.

When this plan was at first conceived, four local savings banks agreed to undertake the financing, construction, and completion of the project. It was understood that the cooperative organization would raise 20 percent of the cost, from the sources above noted. The banks were to accept a purchase-money mortgage to the extent of the other 80 percent. This loan was to run for 25 years at 4 percent, with about 2 percent amortization. The local saving banks were later replaced by the Mutual Life Insurance Co., which was willing to accept 3½ percent in interest, and the plan was modified to the extent that the responsibility for the construction and completion of the project was shifted to the cooperative organization. The insurance company limited itself to a loan not to exceed $5,600,000, or 80 percent of a total cost of $7,000,000.

Under the law, the city agrees to accept the present assessed value (i. e., the unimproved value) of the property as the tax base. The value of the improvements—buildings, and improvements to land—is exempted from taxes for a period of 25 years, after which the association will pay taxes on the full assessed value. The return on investment is limited to 6 percent of the total actual cost.

Cooperators will pay towards maintenance a charge (rental) not to exceed $15 per room; no rent refunds or rebates are to be declared by the cooperative organization during the first 5 years. All savings are to be applied to reducing the mortgage indebtedness. The $15 per room will go to pay interest on the mortgage, depreciation, maintenance, taxes, etc. The "level payment" plan of amortization of mortgage under which the total monthly payments remain constant (but with an increasing amount of this going on principal as interest payments decrease), is to be used to decrease the mortgage liability.

THE BUILDINGS

The East River Development will consist of three 12-story buildings, containing 796 apartments, and a total of 3,047 rooms. Each building will occupy a square block. In addition, one block will be taken up with a garage and a community building to serve the tenant cooperators.

Some of the present streets will be eliminated; others are to be widened. When the project is completed, only one street will cross the development. Children going to school or to the playground will cross only one public street. The buildings will occupy 25 percent of the net land area, or approximately 18 percent of the gross area (including streets). The greater part of the land will be developed as gardens and courts, allowing sufficient air and light in each apartment. With very few exceptions, every apartment will have cross-ventilation and privacy; in each, the rooms are all accessible from a central foyer.

COST TO INDIVIDUAL MEMBER

As noted, the prospective member must subscribe for stock or debentures in the corporation at the rate of $500 per room, and at the time of application must deposit $100 per room as evidence of his good faith. Before construction begins, he must have paid in 50 percent, or $250 per room, and by the time the buildings are completed, the entire amount. The monthly charge of $15 per room will remain constant, and will go towards paying his share of interest, amortization, maintenance, repairs, insurance, etc. After the first 5 years, if that charge should prove to be excessive, the excess is to be returned as a rebate or refund. As the mortgage is reduced, the equity of the member is correspondingly increased.

No method has been devised to assist prospective cooperators who have difficulty in raising the $500 per room. Thus far, only a small percentage of the prospective registered subscribers has signified the need of contracting loans to enable them to join.

PRESENT STATUS OF PROJECT

By mid-November, 1946, more than 75 percent of the apartments had been applied for. Plans had been drawn for the first building (the three buildings are alike in design) and it was hoped that work could be started by the spring of 1947.

With practically the same sponsors and the same management here as in the Amalgamated projects, performance is assured. However, the financial success of the undertaking depends, in essence, upon the price of building materials and cost of labor when construction begins. To stay within the rent limitation, the total actual cost of the project cannot exceed $7,000,000. If material costs rise so high as to bring the total cost above that figure the project will have to be abandoned or modified. Rising price levels have already necessitated a revision of the original financing, resulting in a change of lending agency (i. e., from savings banks to insurance company), in order to economize. On the other hand, if the project succeeds, it may be extended to the East River Drive (Franklin D. Roosevelt Drive)—thus adding an area slightly larger than the one embraced by the present undertaking.

Group Housing Cooperative, Washington, D. C.

Group Housing Cooperative was formed in May 1944. Any person interested in the expansion of cooperative housing is eligible for membership in this organization, upon subscribing for two $5 shares of stock. Membership in Group Housing Cooperative is a prerequisite for membership in any housing project developed by it; however, such membership is not in itself a guaranty of a dwelling nor of membership in any GHC community.

During the first 2 years of its existence the association did educational work in the theory and practice of cooperative housing, with a view to the actual provision of dwellings as soon as conditions permitted. The work was carried on through standing committees on membership, planning, finance, legal matters, public relations, and education.

The association had 411 members by the end of December 1946, with 7 additional applications awaiting approval.

PROCEDURE FOR SPONSORED PROJECTS

Each project which the parent organization sponsors and develops is to be incorporated separately. The function of GHC will be to perform, in consultation with the members, all the preliminaries—land acquisition, provision of legal, architectural, and accounting services, and community lay-out—up to the time when a sufficient proportion (25 percent) of the potential members has invested in the project. At that time a new corporation will be formed whose board will then carry the work through to completion, with the advice and assistance of GHC.

The prospective members of the new community (having already joined GHC) will join the project cooperative, in which each family will have only one vote. Each will subscribe for stock in an amount corresponding to the value of the dwelling selected by it.

It is planned that all of the projects sponsored by GHC shall be "cooperative all the way." Each member family will have a permanent lease on the unit of its choice, but will not hold title to it. If at any time the family desires smaller or larger quarters it will have preference, as regards existing vacancies, over any new member.

BANNOCKBURN PROJECT

Early in 1946 the 124-acre Bannockburn golf course, lying a short distance outside the District of Columbia, in Maryland, which had been taken over by the Potomac River Naval Command and operated as a service recreation center, was put up at public auction.

Cooperators' Properties, an association formed for the purpose of supplying buildings for the use of cooperatives in and around Washington, agreed to act as trustee, receive subscriptions under a syndicate arrangement, purchase the tract, and give GHC a 9-month option on it. It was successful in purchasing the property for $193,000.

Architects were then employed who drew up a plan for a "balanced community" with various types and sizes of dwellings, shopping center, parks and recreation areas, and community center (the clubhouse of the former club).

It was found that, retaining the natural wooded areas and adjacent open land for parks, some 600 dwellings could be provided in the area, with a density of not over 5 families per acre. The community as planned would consist largely of single-family houses, with a few semidetached dwellings, each with 50-foot frontage, and three apartment buildings up to 8 stories in height, each set in a landscaped area of 4 to 6 acres. The provision of various-sized units would facilitate transfer from one to another as families grew or contracted in size.

The total cost was estimated as between 5 and 6 million dollars. It was reported that a large insurance company, interested in long-term financing, was giving serious consideration to placing a mortgage loan on the project.

Local zoning regulations specified single-family dwellings only. The association's application for rezoning the area was denied. Application for rehearing, in April, 1947, was to be made. In the meantime the association decided to go ahead with a small "pilot" development of 18 single-family houses on 4 acres of the land.

Conditions of Membership

The association for the new community, Bannockburn Cooperators, was incorporated under Maryland law in August 1946. As it was not a cooperative law, cooperative features were incorporated in the bylaws. These included nonprofit operation; one vote per member, regardless of the amount of stock owned; and proxy voting (required by the law) only by a member of the absentee's family and no more than one proxy voted by any member. The bylaws also commit the association to fair labor practices in dealing with its employees and purchase of materials through cooperative sources, giving preference to commodities produced under union conditions.

Membership in the association was limited to members of GHC who expect to live in Bannockburn village. Preference was given in the following order: (1) To persons who had subscribed to the purchase syndicate under which the land was bid in; (2) to persons who were members of GHC at the time of purchase, but did not subscribe to the syndicate; and (3) to persons who joined GHC after the purchase. The latter two classes had preference in the order in which they had joined GHC. However, any applicant could be rejected if it appeared that he "or any member of his family unit has shown an attitude inconsistent with the principles or bylaws" adopted by GHC or Bannockburn Cooperators.

Each member must buy 5 shares at $1 each, and make a down payment of $500—$200 at time of admission and $100 per month for the next 3 months (the subscriptions of syndicate subscribers may be applied to this amount). A further payment of up to $50 may be required, but no more thereafter until definite construction commitment has been made for the particular dwelling unit selected. It is expected that the member equity required will range from 15 to 20 percent of total cost.

Priorities in selection of dwelling units are to be in the same order as admission into membership.

In December the new association was sufficiently well organized to take over the property, reimbursing the parent association for its expenditures and assuming the legal, architectural, and other commitments. The association does not plan to begin construction until "materials and manpower are available and prices appear stabilized"—probably not before the summer of 1947 or even later. In the meantime the land is being leased as a golf course at a rental high enough to cover taxes and interest on the mortgage.

Our Cooperative House, New York City

This project arose from the desire of Consumers' Cooperative Services (an organization operating a chain of cafeterias in New York City) to further the expansion of the cooperative movement. Unclaimed patronage refunds (minus taxes) on nonmember business were put into a reserve for such expansion. By 1929, after 9 years' operation, the reserve had grown to over $136,000.

Canvass of the membership indicated housing as a preferred field for action. A piece of land in the Chelsea district of downtown Manhattan was bought and a subsidiary, Rochdale Housing Corporation, was formed to undertake the construction of an apartment house.

The building was a 12-story structure, built in the form of an H, with court gardens, elevator service, roof garden with a view of the Hudson River, and cooperative cafeteria.

Of the 66 apartments, 30 had 4 rooms, there was one 5-room penthouse apartment, and the rest had 1 to 3 rooms each. They were equipped with extra-large windows, electric refrigerators, and many extra "gadgets"; several also had fireplaces. Members were required to invest sums ranging from $1,000 to $4,200, depending on the size and location of their apartment. They received, for this, third-mortgage bonds and a 50-year lease. Original monthly payments ranged from $44 to $65 [7] for 1 room, $66 to $93 [7] for 3 rooms, and $77 to $134 [7] for 4 rooms; these, it is reported, were from one-fourth to one-third lower than those charged for comparable apartments in the neighborhood.

FINANCING

Construction was completed and the apartments were ready for occupancy by October 1930. The total cost was $652,700, of which $190,000 went for land, $395,890 for construction, and $66,810 for fees and financing cost.

The money was raised by a first-mortgage loan of $300,000 from the Bowery Savings Bank, a second mortgage of $130,000 ($99,152 subscribed by members and $30,848 by CCS), a third mortgage of $119,600 raised by the tenants, a fourth mortgage of $37,700 held by CCS, and a loan of $65,400 to run until such time as all the apartments were taken by member-owners.

An association, Our Cooperative House, was formed by the residents and took over the management of the place, on a 50-year lease from Rochdale Housing Corporation.

---

[7] These top amounts were later reduced to $60, $80, and $115.

By the end of the first year 47 apartments had been taken by tenant-owners; the rest were leased to nonmembers. The operations during this period yielded a surplus of $4,364, from which a patronage refund amounting to 3 weeks' rent for each tenant (total, $3,234) was paid.

However, the depression, a factor not anticipated when the project was undertaken, began to make itself felt with greater and greater severity. The financial obligations of membership and even of nonmember rental in the new building were high—more than most people were willing to undertake in view of the great uncertainties of the time. Also, there was a continuous turn-over in membership, resulting partly from loss of employment but also largely from a shifting from job to job, which entailed removal from the neighborhood. The result was that, notwithstanding a rent reduction in 1933 and again in 1937, the association could hardly keep the building filled,[8] much less attract owner-members. Although 47 apartments were taken by owners at the start, by 1931 there were only 31 of these left. The following year the number rose to 38, but this proved to be the peak. Thereafter the number fell off continuously until by 1944 only 11 remained; the other 55 residents were renters.

Notwithstanding these difficulties, the association was run economically and had been able to operate within its income until 1935, when it sustained a loss (of about $1,000) for the first time. A slight recovery for several years thereafter was followed by operating losses year after year, beginning with 1940.

The association had been able to meet its obligations as regards both first and second mortgages throughout the period, however. By 1937 it had reduced its first mortgage to $247,000 and by 1940 to $222,000. In the meantime, however, the parent association, Consumers' Cooperative Services, had had to increase its investment from $133,948 in 1930 to $154,762 in 1937. During the ensuing 3 years Our Cooperative House was able to retire about $5,000 of CCS's second-mortgage bonds and about $4,500 of the loan the association had advanced for members' equity (pending sale of the remaining apartments); this reduced the CCS investment to $148,702 by March 1940.

However, interest on the third mortgage had gone unpaid since 1940 and that on the fourth mortgage since 1937. None had ever been paid on the $10,000 worth of common stock held by CCS.

In 1940 the first-mortgage holder offered a new mortgage with a substantially lower interest and amortization rate, provided the principal was reduced to $200,000. This was done with the assistance of CCS—a process which resulted in raising the latter's total investment in the enterprise to an all-time peak of $166,993, as of March 31, 1942, and in its taking over the operation of the building. With the consent of the second-mortgage holders, the interest rate on their bonds was reduced from 6 to 5 percent. By this time only $26,000 of the $185,000 in third-mortgage bonds was held by members living in the building, which meant an interest obligation on $159,000.

---

[8] This, of course, was an experience common to most apartment houses in the '30s, especially those with fairly high rent levels. In the neighborhood of Our Cooperative House, the banks which had foreclosed on properties in distress lowered rents sharply, wiping out the previous advantage enjoyed by tenants of the cooperative (see p. 25).

This heavy burden, and the additional problems entailed by the war, in the form of increased operating costs and frozen rent levels, made necessary another financial operation in 1944–45, when the organization was faced with the impossible prospect of having to redeem nearly half of the second-mortgage bonds which were to fall due on September 30, 1945. A plan was formulated by which Our Cooperative House was to be dissolved and Rochdale Housing Corporation reorganized with two classes of stock: The common stock ($10,000 in amount), owned by CCS; and nonvoting, noncumulative preferred stock ($100 per share, total $130,000). Third-mortgage holders were offered a choice of preferred stock to the face value of their holdings (in exchange for their bonds) or cash equal to 16½ percent of such face value. It was reported that about two-thirds asked for cash and one-third accepted preferred stock. The plan also met with the approval of the second-mortgage bondholders, who not only voted an extension of time for the bonds coming due but oversubscribed the issue.

This reorganization left the financial arrangement as follows: A 4-percent first mortgage of $180,000, repayable at the rate of $4,000 per year, held by the State Insurance Fund; a 5-percent second mortgage of $121,000, held by 65 investors (CCS holding $20,000 of this); and preferred stock of $130,000, held by 15 investors (CCS holding $90,000).

TERMINATION OF THE PROJECT

As of January 1, 1946, Our Cooperative House went out of existence and this cooperative experiment came to an end. The 9 remaining tenant-owners (who were among the third-mortgage holders affected by the above reorganization) were given 2-year leases at "maintenance rentals." Hereafter, CCS will operate the house (as it has actually been doing for the past 6 years) through Rochdale Housing Corporation. All apartments will be leased and none tenant-owned. In other words, the project has become simply an investment of CCS, not an enterprise run cooperatively by and for resident-members.

A report from the organization to the U. S. Bureau of Labor Statistics stated that, notwithstanding rent ceilings and increased labor and maintenance costs, the reduction in carrying charges and the elimination of vacancies were providing a safe margin in operations for the current (1946) year.

Opinions vary as to the causes of failure. All agree that the primary reason was the dislocation caused by the depression and the consequent unwillingness of prospective members to undertake financial obligations of such magnitude. One of the greatest problems, as one of the original members points out, was only accentuated by the depression. That was the continual shifting of the working population from which the cooperative membership was drawn. This group consisted of social workers, professional people, and high-grade white-collar workers. Even before the depression, they moved from job to job, either within the city or to positions outside. This mobility resulted in a remarkable instability in cooperative membership. Other factors mentioned were the rather high interest rates, maintained after current rates had fallen, the high luxury level of the project, and apartments ill-adapted for general use. Criticism of apartment layout and planning centered in the small size of the bedrooms (not suitable for family use) and in the large proportion of 4-room apartments. Families (counted upon to take the larger apartments) found the neighborhood—which was more suited for single business and professional people and couples—not convenient for raising children. All these factors made impossible the securing of a full tenant-ownership, and without this the project could not succeed.

United Workers' Buildings, New York City

Many years ago a small group of needle-trades workers leased one floor in a house in New York, on a cooperative basis. As the group increased, the whole house was taken over, and certain social features were added and a summer camp was started. These proved so popular that the field of activities was broadened until at one time the United Workers Cooperative Association was the largest and most active cooperative group in New York City.

Beginning in 1925, the association bought tract after tract of land, finally owning 6 city blocks, all bordering on Bronx Park. On this land several apartment buildings were erected.

The first project contained four units surrounding a large central garden, and provided 339 dwelling units. One section of this group consisted of "bachelors' quarters" (single furnished rooms); each 3 of these had a common bathroom and a kitchen was provided for every 12 rooms. The second block of buildings contained 385 apartments and was in the form of an E.

These were 5-story, walk-up apartments. As no wing was more than 2 rooms deep, every room looked out either upon a street or upon the interior garden. Special care was taken to obtain cross ventilation. Less than 50 percent of the ground space was occupied by the buildings. Each kitchen was equipped with gas range, refrigerator, and dumbwaiter; each bathroom had shower as well as tub.

CONDITIONS OF MEMBERSHIP

Membership in the union of the applicant's trade was a prerequisite to joining the housing group. The equity required of each prospective member was $250 per room, half to be paid at the time of joining and the rest within a year. The monthly payment was at the rate of $14 or $14.50 per room, the amount varying according to the location of the apartment chosen.

Originally, the member-purchaser received no stock in the enterprise, but simply a receipt for the amount paid in and a 2-year lease to his dwelling. At the end of 2 years, if he was still acceptable to the other residents, his lease was to be renewed; if not, he had to leave, in which case his principal was to be returned, without interest, minus his proportional share of the cost of redecorating the apartment for a new tenant. Subleasing was not allowed; a resident leaving, for any reason, before expiration of his lease had to return the apartment to the association.

COOPERATIVE AND COMMUNAL FEATURES

Community activities carried on by the association were numerous and varied. They included a kindergarten and day nursery with four full-time teachers; after-school classes in Yiddish and Jewish history for children of grammar-school age, and evening classes in English for the adults of the colony; a "youth cooperative" which arranged for lectures, discussion groups, and various recreational activities, such as concerts, entertainments, hikes, etc.; a community library; an auditorium; a large gymnasium with the usual "gym" equipment, a piano, shower room, locker room, and a room for steam baths; a health clinic; the year-round camp already mentioned (near Beacon, N. Y.) ; collective purchasing of gas, electricity, ice, and milk; and seven cooperative stores—a grocery store, meat market, fish market, vegetable store, delicatessen, laundry, and restaurant. Earnings from the latter were not to be returned in patronage refunds but were to be used for community purposes, as under the Belgian system.

LABOR POLICY

This group had a well-defined labor policy. As already stated, all members were required to be union members, and this requirement was also carried out wherever possible in the business dealings of the association; it dealt only with union companies. All the construction work on the buildings was done by organized labor and the materials were supplied by union companies. The association insisted that even the common laborers employed must be union men. The employees in the cooperative stores, restaurant, and laundry were all members of their respective unions, as were also the teachers in the kindergarten. In one instance the association was responsible for the unionization of a formerly open-shop business—that of the milk dealer from which the dairy products for the colony were bought.

FINANCING AND FATE OF THE PROJECT

The land used for these buildings cost $450,000, and the construction of the buildings planned was estimated at $3,000,000. As noted, each prospective resident had to pay a total of $250 per room. For the first block of buildings, which cost $1,600,000, $250,000 was raised in this way. A loan of $1,100,000 was obtained from the New York Title & Mortgage Co., and the remainder by a 6-percent bond issue of $250,000. This first block was begun in 1926 and finished early in 1927.

The second block was built in 1928. It was financed by a first-mortgage loan, and a bond issue (in the nature of a second mortgage) effected through a subsidiary (Consumers' Finance Corporation) to the housing association.

As indicated in the preceding description, the plans and lay-out were fairly elaborate. Largely because of the high costs, necessitating rents higher than those specified in the New York Housing Law ($11 in the Bronx), the group was unable to qualify under that law for the 20-year tax exemption it afforded. This, of course, meant that a sizable tax burden had to be assumed by the residents.

An attempt was made to organize for the third block under that act, with considerably less-elaborate plans. However, as one observer pointed out, "they had already undertaken more than they could carry through."[9] As the equity payment required was only $250 per member, the net worth of the association was very low, and it appeared, also, that the association had fallen into arrears, on interest, amortization, taxes, and assessments, by over $200,000. The lender instituted foreclosure proceedings. Under a compromise agreement, the land not already built on was relinquished and the association reorganized into the Workers Colony Corporation, with its common stock (the members' paid-in equity) held in trust for the members and its preferred stock exchanged for the second-mortgage bonds of the old Consumers' Finance Corporation—all under the direction of the holder of the first mortgage, the lending agency. The various business enterprises, including the cooperative stores, were sold to private interests or otherwise disposed of.

---

[9] Recent Trends in American Housing, by Edith Elmer Wood, New York, The Macmillan Co., 1931, p. 176.

By 1931 the arrearages had been paid off and the management of the project had been returned to the residents. However, the depression was by then 2 years old and several years of it still lay ahead. Reports to the U. S. Bureau of Labor Statistics indicate that the association never recovered its former ground. Assets at the end of 1941 amounted to $2,383,414, and first and second mortgages totaled $2,201,000. Capital stock (the common stock held by the residents) aggregated $480,525. However, as a result of continued operating losses, by the end of 1941 there was an accumulated deficit of $611,843, more than wiping out the members' equity. At that time about 60 percent of the apartments were occupied by shareholders, and the other 40 percent by renters. Later the mortgagee took over the property and the Workers Colony Corporation was dissolved.

The community facilities—auditorium, kindergarten, gymnasium, library, play room—are still available and utilized by the residents. These activities and the privilege of good housing in pleasant surroundings at relatively low rentals are the sole remaining benefits of the enterprise that started so ambitiously.

Chapter III.—Cooperation in Ownership and Management—The “Mutual” Projects

A “mutual” association, in the general sense of the term, is one that practices the principles of mutuality, i. e., providing goods or services without profit, on a democratic basis, for its members only. Any housing cooperative providing dwellings for its members is thus a mutual organization. Recently, as a result of a plan formulated by Col. Lawrence Westbrook, the term has been used specifically to designate a “system of rental-ownership, under which the occupants of homes in a given community lease the premises which they occupy from a company owned by the occupants themselves.”[1] In such a project the cooperative takes over, for operation and eventual purchase, a completed development.[2] In the projects here described—and in the “mutual” system as visualized by Colonel Westbrook[3]—no down payment is required of the individual member or of the housing association, all the funds being supplied by the sponsor or builder.

The rentals paid cover amortization, interest, insurance, taxes, maintenance costs, administration, and an allowance for vacancies. The tenant thus gradually builds up an equity not only through his payments on principal, but also through certain other credits. Repair and maintenance charges are estimated annually and any excess of actual expenditures is credited to the tenant's account, thus giving him a direct incentive to take good care of his dwelling. His share of the vacancy reserves is also credited to him.

Should he vacate his dwelling during the first year of occupancy, any reserves to his credit accrue to the housing corporation. Thereafter, however, he would be entitled to a refund varying according to the length of time during which he has contributed toward the various reserves and the extent to which these have been or must be drawn against (as for maintenance during his occupancy and renovation for a new tenant). He would also be entitled to repayment of his stock (or principal) equity in an amount equal to the “current price” (i. e., original price depreciated over the period of amortization, less the amount of principal remaining unpaid). A new tenant coming in to take the withdrawing member's place takes over the dwelling at its “current price,” with the same monthly payments on principal as were being made by his predecessor.

---

[1] Mutual Home Ownership for the Veteran, by Lawrence Westbrook.

[2] However, “mutual,” as used in the Wagner-Ellender-Taft housing bill, considered in the 79th Congress but not passed, would have covered any nonprofit housing association providing dwellings for members only.

[3] See “No Down Payment,” by Col. Lawrence Westbrook and George Creel, in Collier's, February 2, 1946.

The mutual arrangement has certain very definite advantages to the member. He is not required to make any down payment whatever beyond, possibly, a membership fee. Should he have a period of unemployment or other difficulties which make it impossible to meet his monthly payments, he may utilize his excess reserves for the purpose, or may borrow against his reserves. As contracts for dwellings are easily transferrable on the books of the corporation, and as units of various size are provided in the projects, a member whose family is expanding or contracting may move from one dwelling to another that is better suited to his needs, with proportionate increase or decrease in total and monthly obligations.

Other advantages of the plan are that each resident, as a member of the corporation, has an equal voice with his neighbors in the affairs of the community; that the plan provides community advantages not generally available to the average individual purchaser; and that it enables the group as a whole to control the property so as to prevent neighborhood deterioration.

No resident ever receives title to his dwelling. Colonel Westbrook emphasizes that this principle is basic. "What he has is the right of perpetual occupancy as long as he keeps up his monthly payments. Anything else would lose the benefit of the system, for with an individual in full control of his property, the community could not enforce high standards."

West Acres, Pontiac (Mich.) [4]

In 1936 the late Senator James Couzens formed a corporation to which he advanced $550,000 with which to buy land and construct 200 houses of varying size and type, in Pontiac (Mich.).

No down payment was required, and the rentals established were "substantially less than the prevailing rental rates." The monthly payment on a 1-bedroom house, for instance, was $32.70 and for a 3-bedroom house $43.80. Nevertheless, it covered amortization spread over a 25-period, interest, taxes, insurance, maintenance, etc., and was sufficient to yield a 3-percent return continuously on the sponsor's investment.

It is declared that in the 10 years of its existence the project, under varied economic conditions, "has tested every basic principle of mutual ownership." Not only did the residents have the benefit of low rents, but without exception families which had to move away realized (through various credits) more than they had paid in on amortization. It is reported that, such was the pride of ownership and so well were the dwellings maintained, the property is now appraised "at well above the estimated 25 to 35 percent increase in production costs since 1936."

---

[4] Data are from Collier's, February 2, 1946.

Public Mutual Housing Projects

Under the defense housing program of the Federal Works Agency, eight projects were designated as "mutual" housing communities; three of these were in New Jersey, one in Pennsylvania, one in Ohio, one in Indiana, and two in Texas. After the creation of the National Housing Agency the projects were transferred to the Federal Public Housing Authority of that Agency.

Although intended to help meet this defense emergency, only such projects were earmarked for "mutual" ownership as were of permanent construction and built to house workers employed in plants regarded as "definitely established parts of the industrial life of the community in which they are located." [5] This therefore ruled out flimsy construction in purely war-born places, which were likely to be abandoned after the war.

The funds used were advanced by the Federal Government under the provisions of the Lanham Act, but all mutual projects were to be self-liquidating from the start and carry no rental subsidies.

The purpose of the mutual plan was two-fold: (1) To enable the Government to dispose of the projects after the war, and (2) to enable middle-income families (i. e., with incomes too high to qualify them for subsidized low-rent housing but too low to permit the making of any sizable down payments on privately built dwellings) to own their own homes. It was considered advisable that the dwellings be placed on a rental basis, under direct FPHA management, with ownership retained by the Government during the war emergency, in order to insure their being available for war workers. However, the Government made a definite commitment, in each of the eight projects, to sell them to nonprofit mutual housing corporations which were formed by the tenants and met certain prescribed conditions.

The accompanying table shows the location, size, and mutual housing status of the eight projects as of December 31, 1946.

At the end of the war, the FPHA pointed out that the war period had offered no conclusive data on the experiment, as none of the projects had yet operated under the direct ownership of the tenants, and only two (at South Bend, Ind., and Dayton, Ohio) had been managed for any length of time by mutual ownership corporations. It noted, however, that these two were "among the most efficiently and economically operated of the Government-owned war housing projects."

---

[5] Article by Colonel Westbrook in Labor Information Bulletin (U. S. Bureau of Labor Statistics, Washington), September 1941, p. 10.

TABLE 1.—*Projects earmarked for mutual home ownership program*

Project and location	Dwelling units	Acres	Total development cost	Status as of Dec. 31, 1946
Greenmont Village, Dayton, Ohio.	500	130	$2,385,000	Mutual Ownership Corporation negotiating for purchase.
Walnut Grove, South Bend, Ind.	250	81	1,149,000	Do.
Winfield Park, Linden, N. J.	700	109	3,704,000	Mutual Ownership Corporation operating under lease, with option to purchase, signed Apr. 1, 1945.
Avion Village, Grand Prairie, Tex.	300	78	920,000	Mutual Ownership Corporation operating under lease, with option to purchase, signed July 1, 1945.
Dallas Park, Dallas, Tex.	300	114	972,000	Do.
Audubon Park, Audubon, N. J.	500	100	2,321,000	Mutual Ownership Corporation, acting as agent for FPHA. Negotiations under way for lease, with option to purchase.
Bellmawr Park, Gloucester, N. J.	500	133	2,119,000	FPHA manager, under direction of regional office in New York City.
Pennypack Woods, Philadelphia, Pa.	1,000	120	4,367,000	Do.

The value of the mutual ownership plan for other public war housing of permanent construction, and possibly for the "greenbelt" towns, is recognized. It is particularly adapted for use in connection with large apartment developments or other multifamily structures in which direct purchase by individuals would not be feasible. In such cases the FPHA would recognize and deal with mutual ownership corporations of residents, provided the corporation can "demonstrate its ability to assure immediate occupancy of at least two-thirds of the dwelling units. As a consumer body, it would be given preference over groups or individuals offering to buy the project for investment purposes." [6]

The corporation.—In order to enter into negotiations for purchase, the tenants must form a nonprofit mutual home ownership corporation.

As a first step toward the formation of such a corporation in a project in which there is sentiment for purchase, a tenants' committee is selected in an election in which every leaseholder in the project is eligible to vote. This committee acts as an organization committee for forming and incorporating the new corporation.[7]

The corporation is run by a board of nine trustees—three representing the public, three the residents, and three the Government. During this period the trustees formulate bylaws, receive membership applications, and issue membership certificates. When the residents have joined in sufficient proportions to indicate that the time is ripe for putting the mutual ownership plan into effect, the FPHA is requested to lease the property to the corporation, with an option to purchase at the end of 2 years' operation. This 2-year period is designed as a testing time in which the corporation, under FPHA supervision, masters the problems of management and learns to carry on independently.

---

[6] Statement issued by FPHA.

[7] The Federal Public Housing Authority of the National Housing Agency, Washington, D. C., will assist the tenants during this stage, by providing information on the plan and technical advice on the mechanics of forming a sound corporation.

The lease obligates the board of trustees to manage the project in conformity with FPHA regulations and policies for operation and maintenance, set forth in the lease, and under a budget approved by that agency.

The board also collects the rents from the residents and from these it pays all the operating expenses. The margin between revenue and expenditure is paid to the FPHA, to cover interest and depreciation; if the margin exceeds the cost of these two items the surplus is credited, to be applied (at the time of final sale to the corporation) in reducing the purchase price to the corporation.

At the end of the 2-year period the corporation may exercise its option to purchase. The purchase price is set by two appraisers, one representing the Government and the other the corporation; if they cannot agree they appoint a third person mutually satisfactory, whose decision is final.

Conditions of sale.—No down payment is required. At the time of sale the corporation receives title to the entire property, but gives the FPHA a mortgage for the entire purchase price and a promissory note for which the mortgage is security. These obligate the corporation to make, over a period of 45 years, monthly payments totaling approximately one forty-fifth of the purchase price per year, plus 3 percent interest on the unpaid balance.

Although the Government retains certain controls over the management, in order to protect its investment, considerable responsibility is vested in the members from the outset.

Cost to member.—The member pays a membership fee of $50 at the time of joining the organization. He signs a contract, binding himself to purchase, on an installment basis over a 30-year period, stock in the corporation equal to the value of the accommodations he plans to occupy. He is given a lease on the dwelling of his choice, running for as long as he continues to occupy it and make his payments. These payments consist of a monthly rental which covers 3 percent interest, insurance, taxes, administrative expenses, reserves for maintenance and contingencies, and the payment on his stock subscription. As fixed amounts are paid on the principal each month, the interest payments (which are figured on the unpaid balance) continuously decrease. When the member has paid up the entire principal, his monthly payments will include only the cost of taxes, insurance, maintenance, and repairs. Since the tenant is paying off his obligation in 30 years, whereas the corporation has a 45-year period of amortization, he enables the corporation to make prepayments on the principal owed to the Government, thus building up an advance equity or "cushion" for use in times of adversity.

GREENMONT VILLAGE, DAYTON, OHIO

On October 1, 1945, at the expiration of the 2-year lease, the Greenmont Mutual Housing Corporation exercised its option and notified the Government of its desire to purchase. Negotiations over a period of a year were expected to result in a contract to purchase, for approximately $1,500,000, the 130-acre tract containing 500 dwelling units and recreational and community facilities. As of mid-September 1947,[7] all but 12 of the 500 resident families were members of the corporation. These 12 will eventually have to vacate in favor of members unless they decide to join.

The community is laid out in the form of a circle, with dwellings in small groups on cul-de-sacs where children may play safely, away from the main thoroughfare that swings in an arc through the project. At the northwest corner of the tract are the new community school, the community buildings, and the shopping center.

In the center of the tract, space is provided for recreational activities. A tennis court was being laid out at the time the project was visited, and one large area was used by a group of airplane-model enthusiasts. Opportunity for further beautification and recreational facilities is offered by a creek (overhung by scattered trees and crossed by several foot bridges), which runs through the tract.

Dwellings—facilities and costs.—The dwellings consist of 1-story single and double houses and 2-story double houses of rectangular shape and flat-roof construction. Relief from monotony is obtained by interspersal of buildings of different heights and sizes, by the use of exterior paint of different pastel colors, and the varying use by the tenants of flowers and shrubs in the yards. A 2-foot layer of insulation under the roof and 6 inches of water keep out the summer heat.

Every dwelling unit has a living room, utility room, kitchenette, and from one to three bedrooms. Monthly rentals are as follows: $27.50 for a 1-bedroom unit in a double house, $30.00 for a 2-bedroom unit in a double house, $32.00 for a 2-bedroom unit in a single house, and $32.50 for a 3-bedroom unit in a double house. These rentals are calculated to cover amortization as well as upkeep. Operating expenses at Greenmont have been kept low, averaging $10.86 per dwelling per month during the year ending September 30, 1945. This figure included expenses of management, janitorial service, utilities, repairs, replacement, maintenance of grounds and structures, waste removal, and insurance.

---

[7] When the project was visited by a member of the staff of the Bureau of Labor Statistics.

The average cost per dwelling was $4,793, of which $161 was cost of land, $127 went for architectural and engineering costs, $935 for site improvements, and $3,220 for construction of the dwelling and equipment, $248 was cost of community buildings, and miscellaneous items averaged $102 per dwelling.

Community buildings and services.—The administration building contains, besides the office of the project manager, a large hall where community meetings are held, movies (mainly for the children of the project) are shown, and the various organizations of the residents (women's club, boys' club, men's club, veterans' group, etc.) hold meetings and recreational and social events. The building also contains rooms for smaller groups, space for several overflow classes from the school, and a large well-equipped kitchen from which refreshments are served on social occasions.

A smaller building near by houses the child-care center. Here a staff of five, hired by the corporation, care for the smaller children of the community. The center is open from 6 a. m. to 6 p. m. It provides breakfast, lunch, and afternoon snack, supervised play and rest periods, and classes in music appreciation, singing, and drawing. Its charges (for a 6-day week) for children of residents amount to $5.50 for children who receive lunch and snack and $6.25 for those who also receive breakfast; for nonresident children $1 more is charged. Up to 40 children are being cared for; at the time of the visit of the Bureau's representative, 33 children were present and were taking their afternoon rest on cots in a large, airy room. Quarters and equipment were provided by the corporation; otherwise the center is self-supporting.

The commercial center, at the edge of the tract, contains a privately owned cleaning establishment and barber shop. and a cooperative association which operates a meat and grocery store and a new drugstore. The latter also serves lunches, ice cream, soft drinks, etc., and is planning to add a household-appliance and small-hardware department. In September the grocery store was averaging about $12,000 in sales per month and the drugstore about $1,500 per week. The association has been handicapped by supply difficulties and by inadequate capital. Some 325 families are members.

WALNUT GROVE VILLAGE, SOUTH BEND (IND.)

In mid-September 1946, appraisal of the Walnut Grove property was in process, the Mutual Housing Association having completed its 2-year probational period. All but 12 of the 250 families resident in the village had become members of the association.

The community lies at the edge of the city of South Bend, Ind., between two main highways. The thoroughfare of the village leads in from the highway to the west, at the north edge of the village, and swings in a horseshoe curve through the tract, coming back to connect with the same highway at the south side of the tract. A small curving road gives access to the east highway at the top of the horseshoe arc.

Dwellings—facilities and costs.—The dwelling units are set diagonally on either side of cul-de-sacs which lead off, also diagonally, from the thoroughfare. Some diversity is produced by the use of various levels and sizes of buildings. All the buildings, however, are of dark-stained, frame construction, so that the general effect of the village is not so pleasing as at Greenmont. The same style of architecture—porchless and with flat roofs—is used as at Greenmont.

The rooms are at two different levels, kitchen and living room being at ground level, whereas the bathroom and bedrooms are several steps higher. The elevation of these latter rooms provides space for a small basement and enables cross-ventilation in the bedrooms through small high windows which are set into the wall where these rooms rise above the lower-level rooms.

Rents are the same as at Greenmont.

Community buildings and services.—The administration building lies at the west side of the tract, between the two ends of the thoroughfare. It contains a meeting room and the cooperative store, as well as the office of the manager.

A space has been set aside, near the east entrance road, for a baseball diamond, and plans have been drawn for a small stadium there. Swings, slides, and sand boxes are scattered here and there for the children.

Chapter IV.—Housing with Self-Help Features

Penn-Craft (Pa.) Community

The Penn-Craft experiment dates from the spring of 1937 when the American Friends Service Committee [1] undertook a housing project for 50 families of coal miners. Its declared purpose was to aid in "finding greater economic security and better social life for the great body of industrial workers in this country."

The economic life of the region in which Penn-Craft is situated depends on the mining industry. Private trade, banking, and railroads thrive when the mines are working and languish when they are idle. Mine activity, on the other hand, is dependent on industrial activity and is greatest when the country's industries are busy. Many of the mines in Fayette County had been worked out and closed down by the time the project was started, and others active during the war but no longer profitable to operate have been closed down since. Nevertheless, extensive coal fields are still available in the vicinity and across the Monongahela River.

The problem of displacement and unemployment therefore is not immediate, but must be faced eventually. The sponsors of the project, anticipating that time, hoped not only to demonstrate the possibility of improving the living conditions of the miners through self-help, under competent disinterested supervision, but also to insure a cushion (in the form of subsistence homesteads) against hard times. The project was to be an experiment in education, utilizing the spare time of the miners to provide new and better housing owned by themselves and eventually leading to greater family self-sufficiency with decreasing dependence on paid employment.

The work has been carried out in two projects, the first on 200 acres of farm land in Fayette County near Republic, Pa., the second (now in process) on 165 acres near the first property. In both cases financing, management, and supervision were provided by Friends Service, Inc., a nonprofit organization. Procedures for the two projects have in general been the same. The chief differences lie in the size of the individual holdings (the 1½–3-acre homesteads in the original community have been increased to 10-acre holdings in the second tract, in the interests of greater economic security for the families), in the removal of certain subsidies that were extended in the first project, and in the adoption (in the second project) of a sliding scale of repayments that takes account of financial emergencies affecting family income.

---

[1] This committee was organized by the Quakers in 1917 "as an avenue through which young men and women of the Society of Friends could express their desire to help their fellow men, not by bearing arms and participating in war, but by helping to heal the wounds of war." The program of child feeding in the bituminous-coal fields, undertaken in 1931–32, at the request of President Hoover, led the committee to become interested in means whereby unemployed and partially employed miners could produce their own food from the land and develop new skills as a source of cash income. The project here described was the outgrowth of that interest.

SELECTION AND CHARACTERISTICS OF HOMESTEADERS

In the first project only coal miners were eligible. Each applicant family was required to furnish rather detailed information about itself. In selecting the homesteaders, consideration was given to age, financial resources, life expectancy, and productive capacity of the family. In families having no financial resources, it was required that there should be an "evident family production for a period of 10 to 15 years."[2] A basic requirement was that the applicants must either be citizens of the United States or take immediate steps toward naturalization. Medical examination was required of all the members of the family before final acceptance.

Preference was given to applicants from Luzerne and Redstone Townships and the area immediately surrounding, but there was no discrimination as regards race or creed. The result was a community that included various religious faiths and Negroes as well as whites. At least three-fifths of the settlers were of English, Scotch, or Welsh descent and the remainder included Slavs, Poles, Irish, Germans, Italians, and French—a cross section of a typical mining community in this region.

In the assignment of the land, the homesteaders drew numbered slips entitling them to choice in the order indicated on the slip drawn. Thus, the possessor of No. 1 was entitled to first choice among all 50 plots, No. 2 to choice among the remaining 49, and so on.

In the second project, selection is on the same basis as in the first, except that nonminers are being accepted as well as miners.

THE HOMESTEADS

Each homestead in the first project contained a dwelling, poultry house, and other outbuildings. As the miners' families are generally large, the dwellings are good-sized 2-story stone buildings, each with modern kitchen, living room, bathroom, and 2, 3, or 4 bedrooms. Each bedroom has a large closet. Each house has electricity, a front or rear porch, and a full basement containing a central heating plant, laundry facilities, and food-storage space. Some of the houses have garages built into the side of the basement.

---

[2] One exception was made to this, for a family consisting of an older man and his wife, in view of certain exceptional considerations.

Houses in the second project will be of the same size, or larger, and will have the same facilities.

In the first project the red stone native to the locality was used as building material. In the buildings under way in the new tract, cinder blocks are being used, because of the smaller amount of labor required. With mines running full time and employment at a high level, labor time is at a premium and cannot be spared for quarrying and shaping the stone, whereas the cinder blocks can be made quickly and cheaply by unskilled workers and are regarded as satisfactory.

In the first project, a standard plan was used for the 4- and 5-room houses and two plans for the 6-room dwellings. Variety in appearance was obtained by reversing the plans, shifting the location of the porch, garage, etc. In the second project, use is being made of plans of rural houses drawn up by the former Farm Security Administration.[3]

The land plots of the first 50 homesteads ranged from 1½ to 3 acres, depending on the topography of the ground. This furnished space sufficient to raise a substantial part of the family's current food as well as some to store for winter. Additional garden space, if desired, was available in the belt of land reserved for farming and gardening. It is expected that the families in the new section, where the homesteads average 10 acres each, will in times of steady employment use the extra land for the pasturage of dairy and/or beef cattle, sheep, pigs, poultry, etc. When jobs are scarce the land can be utilized for more subsistence crops. It is explained that the purpose of the second project is the further demonstration of "the value of land as a backlog of security" and that Friends Service desires that production for home use be emphasized "at all times * * * as the thing of first importance."[4]

FINANCING, AND TERMS OF CONTRACT

Upon becoming a participant in the homestead project, each family signs a lease agreement with Friends Service, Inc.

The present lease agreement differs in certain respects from that used in the building of the first group of houses. The corporation still obligates itself to supply engineering service, supervision, and direction of construction and installation of all public improvements, and such skilled labor as is necessary. Previously, however, it supplied the first two of these items, as well as the heavy tools and equipment, without cost to the home owner. This subsidy has been withdrawn, it being the feeling of the corporation that the project should stand on its own feet. Therefore the prospective home owner is now charged $15 per month for "overhead" from the time he signs the lease agreement until he moves into his completed dwelling.

---

[3] Small Houses (U. S. Department of Agriculture, Farm Security Administration). Blueprints of houses contained in this pamphlet are available, on payment of a small charge (30-70 cents) from the Extension Agricultural Engineer, New Jersey State College of Agriculture, New Brunswick, N. J.

[4] Statement issued by David W. Day, manager of both the first and second projects.

Originally the corporation agreed to advance a cash loan of $2,000 to each member, of which not over $300 could be used for the hiring of the skilled labor necessary in construction, the remainder being used for building materials, outbuildings, cost of land, the homesteader's share of the cost of water system and roads for the whole project, and some small equipment; the loan may also be drawn upon for temporary housing, pending completion of the permanent dwelling, but must be repaid at the rate of $10 per month. In the new agreement these sums are raised to $2,500 and $500, respectively, and in the second project a down payment of $500 is required.

Under the original agreement the homesteader was to repay his loan (beginning when he moved into his finished house) over a period up to 20 years at the rate of $1 per month for every $200 borrowed; this amount included interest at 2 percent. A "variable payment" plan is provided for in the new lease agreement, which relates the monthly payments on the cash loan to the family income. In prosperous times the family may repay its loan as fast as its income permits. In hard times—subject to a required minimum payment of $48 in any consecutive 4-month period—the payment may drop to as little as $1 per month if the weekly gross earnings are between $5 and $10, or to nothing if they fall below $5.

The second lease agreement runs only for 1 year after date of occupancy, during which time the homesteader will pay the corporation a rental which will include interest at 4 percent. At the expiration of the year period, the leaseholder may exercise an option to purchase the homestead, in which case the corporation will assist him to refinance his cash loan, using the regular loan agencies to do so. From the proceeds of the refinance loan the corporation will be repaid in full, thus enabling it to turn over its funds more quickly and go on to further demonstration projects. In the original project, as noted, the corporation's funds were tied up for periods up to 20 years. At the end of that time, or sooner, if the homesteader paid up his loan more quickly, the latter would receive title to the property in fee simple, but not until his entire loan was repaid.

Under both lease agreements the homesteader agrees to contribute his own labor, and that of members of his family, toward the construction of his house and the houses of the other homesteaders; to make his required monthly payments; to keep the premises clean and in good repair; not to allow them to be used for any purpose obnoxious or detrimental to the community; and not to sublet or lease the property for commercial purposes except with the approval of the management (corporation). Further, in the new lease (in order to eliminate long lapses of time during construction) the leaseholder binds himself to build a house "ready for occupancy," within a period of 18 months from the time he signs the agreement.

LABOR SUPPLY, AND TERMS OF THE "LABOR LOAN"

All the work has been done under the direction of the project manager appointed by Friends Service. He assigns the available workers to the various types of work in process at any given time, purchases all necessary supplies, and determines the order of progression of the work.

In all the construction processes, the labor of the adult members of the family and of sons 16 and 17 years of age (formerly 15–20 years) is used. The labor of adults is reckoned in terms of man-hours; that of the youths in terms of "boy-hours," one boy-hour being equivalent to three-fourths of a man-hour.

In theory the expected labor performance of the homesteader (or his sons) is at least two 8-hour days per week. Actually, the amount has varied widely, depending largely on the extent of paid employment at the mines and therefore on the free time available to the homesteader.

At the end of each day the amount of time spent at work at the project is reported by the homesteader to the office and is entered to his credit. If it was spent on the dwelling of another colonist, it is also entered as a debit against the latter's account. Once a week each homesteader receives a statement showing the status of each of the houses, in terms of labor-hours. This statement shows for each homestead the date the colonist was accepted into the project, the total hours he has worked since that time, the time worked during the week for which the report is made, a "progress estimate" showing the hours that would stand to his credit if the colonist had put in the two 8-hour days a week regarded as standard, the total "purchases" in labor-hours spent by other homesteaders on the house, such purchases during the week of the report, and the balance of labor-hours still owed. Once a month he receives a statement showing the labor hours worked on his house and by whom. Statements are also rendered upon completion of each portion of the work, showing the status of the cash accounts.

Each homesteader binds himself in the lease agreement to repay the amount of time spent on his house by an equal amount worked on his neighbors' dwellings. Failure to carry out this promise may (as for failure to meet rent payments) result in expulsion from the project.

No homesteader, having repaid his labor debt, is allowed to accumulate more than 100 labor hours' credit thereafter. This surplus is used for extra labor, such as for grading of lawns, laying of sidewalks, making driveways, etc., needed after the house is completed.

EVOLUTION AND PRESENT STATUS OF THE COMMUNITY

In the original project, in 1937, the nonprofit organization, Friends Service, Inc., which was formed to provide management and supervision, used contributed funds to purchase a 200-acre farm, 2 miles southwest of Republic (near Uniontown), Pa. The purchase included the land, which was roughly in the form of a shallow bowl, a large red brick house, a small dwelling more than 200 years old, and several outbuildings. The center section of about 100 acres was divided into homestead plots of 1½ to 3 acres each. The rest of the land was kept for woodland and for farming, grazing, and the raising of hay and feed for the homesteaders' cows and poultry.

Before any work could be started on the dwellings, however, much "community" work in the form of roads, utilities (water, sewer, electricity) and clearing out of brush had to be done and this labor served as a try-out test for the applicants.

How the houses were built.—Only two workers were on a cash basis; these were a skilled mason and a carpenter under whom, as gang foreman, the homesteaders and their sons worked. The plastering was done by the homesteaders under the direction of a plastering contractor hired by the corporation. Most of the homesteaders were unskilled in construction work, but the specialized skills of one or two members (an electrician and a carpenter) were utilized.

The costs were minimized by making as complete use as possible of materials and resources at hand. In the first project native stone available on the site was quarried and cut by the men, and the sand used in the cement work was crushed in the community's own stone crusher. In the new project, because of lack of labor time for quarrying and shaping the stone, cinder blocks are being used as construction material. These are made by the men themselves on a simple machine.

Some 70,000 feet of timber has been cut from the community's woodland; a local sawmill cuts this into lumber of required sizes.

Various labor-saving and simplifying devices have been used to enable the unskilled homesteaders to do as much of the work as possible. Thus, the project manager devised a movable form (see diagram, p. 84) by the use of which the men could lay the stone in the walls quickly and satisfactorily without supervision by a skilled mason. It is estimated that this saved some $200 per house. Interior trim, door and window frames, etc., were made by the homesteaders themselves from odd lots of lumber obtained at bargain prices. Improvements in skills and processes resulted in steadily reducing costs. Thus, the first foundation cost of about $117 was eventually reduced to about $30.

Progress of the work.—Excavation on the first basement was started in August 1937. Because the mines were fairly active and the miners' free time therefore limited, the construction was slow. The first house was not ready for occupancy until November 1940.

In the meantime, in order to obviate so much travel between the mine village where the prospective homesteaders were then living and the site of operations, it was decided that the poultry house that was to be a part of each homestead should be built first—and that this be used for family quarters until the house proper was completed. These buildings furnished shelter during the construction period and in a few cases were still being occupied in September 1946—by the families of veteran sons of original homesteaders.

By the summer of 1943 all 50 houses were occupied, and the project as originally planned was complete. Since then a further step toward greater family self-sufficiency has been undertaken and is now under way. A nearby farm of 165 acres has been bought and divided into 15 homesteads of 10 acres each. By September 1946, 11 of the new homesteads had been applied for; 8 of the applicants are ex-servicemen. Work was already in progress on 2 of the homesteads at the time they were visited.

The Penn-Craft homesteaders in the original project have spent the time since completion of their houses in landscaping their places and paying on their cash loans, and have made good progress. Thus, with the average expenditure of some 2,750 labor hours and $2,000 in cash they have been able to obtain well-built stone houses that were estimated in 1939 to be worth from $3,000 to $4,000 and would bring at least half again as much today (see fig. 1, p. 47).

ACCOMPLISHMENTS AND PROBLEMS OF THE COMMUNITY

One has only to compare the attractive, substantial dwellings scattered over the gently rolling green land of Penn-Craft Community with the unpainted shacks standing in stark rows, unrelieved by grass or trees, in the nearby mine "patches" where the homesteaders formerly lived, to realize what a long step upward this experiment has meant in their scale of living.

Under the original plan the minimum monthly payment is $12.58 per family, but most of the families have paid at a considerably higher rate. In September 1946 not a single family was in arrears, and seven had completed their payments and received the deed to their homestead. Two houses had been sold, one to the homesteader's son.

Lease modifications in the light of experience.—The original lease contained no restriction on sale, it being felt that opportunities for the sale of property in a community as small and as isolated as Penn-Craft would be so few that that fact alone would tend to prevent unduly high sale prices. Experience under the plan made some restriction and other changes seem desirable. Under the new lease agreement the leaseholder agrees not to sublet or assign his interest without the consent of the managing corporation. In the event of his death or of circumstances necessitating his removal from the project the management is to "cooperate in endeavoring to find a suitable successor

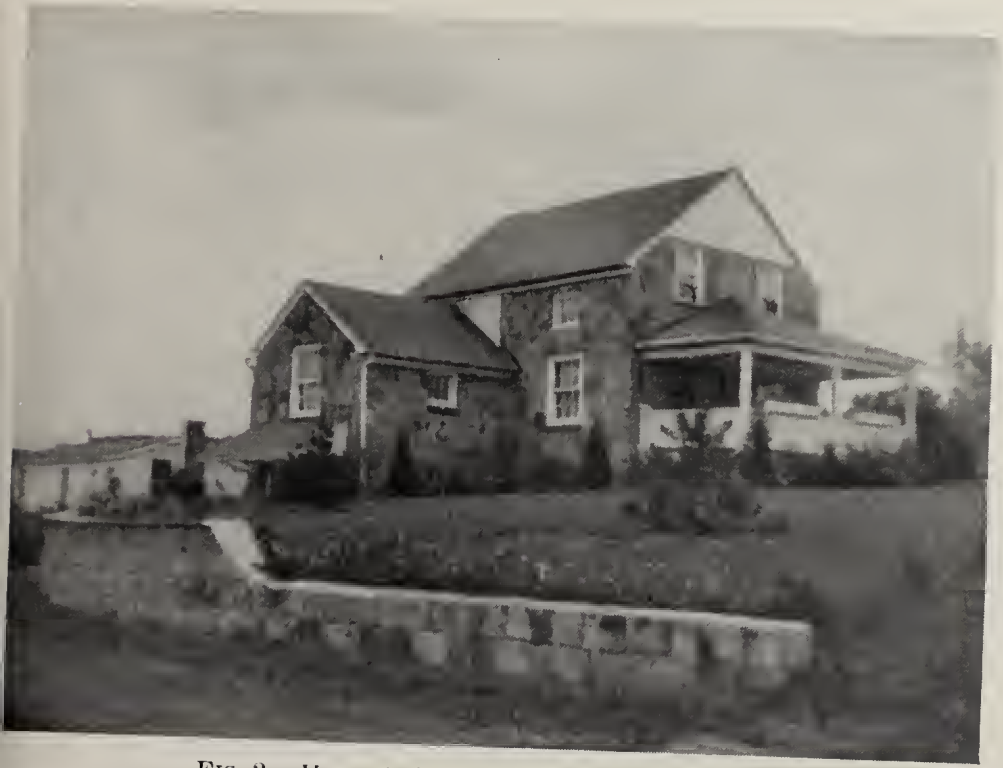

FIG. 2.—House built by self-help at Penn-Craft.

o take over the homestead." All questions regarding other restric-ions on the property are to be decided by a "Restriction Committee" omposed of five members—homesteaders—elected by vote of the omestead association members.

A revised lease with the same restrictive features, has also been rawn up for the first-project homesteaders. By September 1946 ll but 8 of the 50 had signed such leases.

Community life and activities.—Each family becomes automatically member of the Penn-Craft Community Association (the original roject) or the association that will be formed to have general manage-ent of the new project. The community association functions like the old "town meeting," at which questions of community interest, regulations regarding members' obligations and rights, and other matters are discussed and decided.

Community activities center in the brick building which was originally the farm residence. A well-baby clinic and maternal health program, started in Penn-Craft, has become part of a larger, better-equipped center in the nearby town of Brownsville.

Cooperative enterprises.—The Penn-Craft Cooperative Store, started with 5 members and a capital of $25, soon after the project was undertaken in 1937, grew slowly. It had 20 members (and 30 partly paid up) and $150 capital by the middle of 1939; a year later its membership had increased to 54 and its capital to $256. Originally, membership was limited to families living on the project. This, however, as the preceding figures indicate, placed a very definite limitation on the size and usefulness of the association. Membership was therefore thrown open to persons in the surrounding localities, resulting in a quick expansion. By September 1946 the association had nearly 500 members and was doing a business of some $7,000 per month. A new building has been constructed, and it is occupied by the store and a cold-storage plant which is a department of the store. This plant has 340 lockers, all rented; an addition of 215 will be built as soon as sufficient capital is raised. Lockers rent for $12.50 per year. As the facilities are expensive to build, locker patrons, even though already shareholders in the store association, are required to contribute $35 capital each. Much of the surplus garden truck, formerly canned by the housewives, is now being frozen and stored in these lockers. When the Bureau's representative visited the plant, in September 1946, several whole slaughtered beef animals, not yet cut up into meat, were hanging in the big freezer room. Practically all of these and the meat contained in the individual lockers, according to the project manager, came from animals raised by the members. The amount of such production will be considerably increased in the new 10-acre homesteads if present plans are carried out. The credit union started in mid-1940 was not successful and was liquidated. Another is now being planned.

Sources of cash employment.—The coal mines, of course, are the main source of cash employment, but the community has one industry of its own—a knitting mill specializing in women's sweaters. This factory, a large well-ventilated well-lighted plant, was built by the homesteaders, each donating 100 hours of work. It was forced to suspend operations during the war, because of inability to obtain yarn of the quality needed but is now leased to a private employer.

Here 80 people are employed; as the community cannot furnish sufficient number of workers, some 70 percent are from the territory around Penn-Craft. The girl employees earn from 80 cents to $1.00 per hour; the boys earn up to $1.07. The workers have recently joined a United Mine Workers District 50 local. The mill is running full time, and has a good market. Its output is divided about equally among the New York, Chicago, and San Francisco markets.

The community farm, previously operated by the management, has been sold to a young homesteader.

Iona (Idaho) Self-Help Cooperative

To fulfill an urgent need for habitable living quarters, for amounts which they could pay, 15 families in Iona, Idaho (later joined by 6 others) undertook a self-help housing project in 1934. A small revolving fund was obtained under the State-Federal self-help program in effect at that time, and this was used to make loans to members for housing purposes.

CONDITIONS OF LOAN

Under the plan, each participant was required to own a lot with title clear. Upon fulfilling this requirement he received a cash loan from the revolving fund in an amount not exceeding $500, plus a loan of cooperative labor (i. e., part-time assistance in the construction of his house by his fellow members). If his application was favorably received by the cooperative, it was forwarded to the State corporation and his lot was deeded, as security, to a disinterested trustee acceptable to him and to the corporation. The cash loan was made available and the materials necessary for construction were purchased by the cooperative's bonded accountant, so that the actual money did not pass through the hands of the borrower.

Construction was usually begun in a slack period when other employment was not available. On a particular dwelling the labor contributed by the borrower's fellow cooperators was charged against him and credited to their individual accounts on the books of the cooperative, at the rate of 30 cents an hour. This labor had eventually to be repaid by the owner with his own labor on other members' houses.

The cash loan usually had to be repaid over a period of from 2 to 5 years. Payments ranged from $3 to $10 per month, which was generally less than the amount previously paid in rent. When the loan was repaid and the labor claims also satisfied, the borrower received title to the property.

Generally, three loans were necessary to provide for the construction of a complete house. The first loan provided the concrete basement, which was arranged into several rooms—ordinarily, kitchen, living room, and two bedrooms—so that it could serve as living quarters while the first loan was being repaid. The second loan covered the cost of the shell of the superstructure—walls, roof, and windows. The third loan provided for the material for finishing the dwelling. The houses were equipped with cesspools (as there was no general sewage system in the vilage), running water, and electric lighting. All of these represented luxuries, compared to the conditions under which the members formerly lived.

Thus, in a period of 6 to 10 years the family was enabled to pay for a home worth some $2,000 to $2,500, without owing more than $400 to $500 in cash at any one time or paying more than $12 in interest in any year. The exchange of labor of course accounted for a very great reduction in the cash outlay otherwise necessary. Such labor was carried on under the guidance of a carpenter member. Also, in order to reduce cash expenditure, the members salvaged materials from old buildings being demolished, made building blocks, utilized native stone (replacing the concrete originally used, which had to be purchased), and effected various other economies.

In case of sickness the borrower was given an extension of time on his loan. In order to protect the families in case the breadwinner died, the association adopted a plan of "widows' insurance." Under this plan each borrower paid 10 cents a year on each $100 of his cash loan still owing. If the borrower died, the association would take a mortgage in the amount still owed and give the widow a deed to the house, permitting her to live there the rest of her life without further payment. Upon her death the heirs could obtain possession by repayment of the mortgage; failing this, the house would revert to the association.

The housing project was successful and made earnings from the start. In the first 6 years of operation the revolving fund grew (by payment of interest, fines for delinquency, etc.) from $1,650 to $3,000. Although the fund provided sufficient money to finance the participating group, one of the leaders pointed out that "if there had been more in the fund we could have touched more people. As it was, we had to limit our membership growth to those we had funds to serve."

OTHER JOINT ACTIVITIES

The success of the housing venture led the group to look about for other ways in which the living standards could be improved by cooperative means. Medical and dental care were obtained under a plan worked out with two local physicians and a dentist, by which each member family could obtain up to $50 worth of care. The bill was covered by a rider (or mortgage) on the house contract, payable after payment was completed on the house.

A credit union (with about $100 in capital) was started and not only aided in the credit problems but assisted in a food-conservation program which the group undertook. Garden plots were worked to produce food for the families' consumption. In the spring of 1938, each member family pledged itself to store, by 1940, ten 10-gallon cans of nonperishable food, and to raise, each season, one animal to butcher. This was "in anticipation of future economic depressions," and with the idea that it would enable the family to weather 6 months without distress.

One member wrote, regarding his participation in this program—

> I just butchered our self-help pig which gave us 315 pounds of meat. We have enough lard to last our family a year; also some bottled sausage. We will have our winter's meat and two cured hams and some salt bacon for next summer. We fed this pig lots of weeds from the garden and scraps from the house, together with $6 worth of wheat, and we sold a litter of pigs for $40. We have on hand now 600 pounds of flour, 30 sacks of potatoes, 400 pounds of squash, about 100 pounds of dried beans, together with a lot of carrots, dried corn, onions, cabbage, etc. We have only 1 ton of coal, but we have cut enough willow to last us 3 months.

At the end of 1938 some of the families still had insufficient milk and butter. The group therefore voted that every family without a cow must take a loan of $5 from the credit union. This was to be used for the purchase of a heifer calf, in the spring of 1939, to be raised as a source of these products.

Thus, in the course of the program, the families learned to work together for their own benefit and for social purposes. By helping themselves they improved their living standards, raised their morale, and learned new skills which contributed to their economic rehabilitation.

Oakwood Community, Chapel Hill (N. C.)

The project at Chapel Hill was directed by the Service Employees Corporation, a private organization whose stockholders were key men in the business organization of the University of North Carolina. This corporation was formed in 1936 for the purpose of providing social and recreational facilities. The corporation having assisted three employees to obtain building sites on easy terms, one of its officers conceived the idea of providing houses, largely on the basis of exchange of labor, for the building service and maintenance workers employed by the university.

Membership in the housing group was limited to employees in the university service plants (building-maintenance department, laundry, service stores, and accounting, purchasing, and clerical divisions) and the university auxiliary enterprises which serve the university and the town of Chapel Hill (water department, telephone exchange, and electric light and power production and distribution).

The housing scheme was launched in March 1940. Employees who wished to participate were invited to come together and organize themselves into the "Employees Housing Group #1." Members were to work together under a foreman selected by themselves, the project being under the auspices of the Service Employees Corporation. A 40-acre tract of land, about 2 miles from the center of Chapel Hill, was obtained for $2,200 and was christened "Oakwood." Part of the ground was laid out in 50 plots 125 by 160 feet. The lots were priced at $210 each and were distributed by the drawing of lots. It was planned to erect the houses, 3 at a time, in the order of the number drawn. Thus, holders of lots Nos. 1, 2, and 3 were to have their dwellings built first, then those of Nos. 4, 5, and 6, and so on.

Under the plan the amount to be expended on materials was limited to $2,000 per house, and no loan could exceed 2½ times the borrower's annual income or a maximum of $4,500.

An architect was engaged at a fee of 2 percent of the cost of construction— a saving of 2 percent. Bids for the main structure of the houses were let on contract. The Service Employees Corporation purchased the building materials and supplies on competitive bids, and the fixtures and equipment for the houses were bought through a local wholesaler at a saving of about 25 percent. All of the road building, clearing, grading, and basement and septic-tank excavation was done by the participating members, as well as the painting, electric wiring, and installation of the plumbing and the heating system.

Labor accounts were kept in terms of hours worked, the member receiving credit for time worked on other members' dwellings and being debited with hours worked by them on his house. The project was financed from funds of the Service Employees Corporation, by loans from an insurance company, and by FHA insurance. Title to the property was retained by the corporation until each participant had satisfied his labor debt. When that was done, the member received a deed to house and lot and was financed for the exact amount expended on it.

The project involved a total of 14 houses of brick or frame construction, in a variety of styles. These dwellings ranged in cost from $2,750 to $5,000, or about 25 cents per cubic foot. The labor cost of the typical house of five to six rooms averaged about $1,200, of which the personal labor of the members accounted for about $500.

The member had to make a down payment of 10 percent of the total value, but of this the cost of the lot constituted a considerable proportion. Initial monthly charges on a typical house averaged $21.54 plus $1.80 for taxes and insurance, or a total of $23.34.

Watsonville (Calif.) Project

This project was initiated by two businessmen (brothers)[1] of Watsonville, but involved a considerable amount of self-help by the families which participated. The idea originated in 1938, as a means of retention of four skilled workers on the farm of one of the brothers, as well as of disposal of surplus land in their grandfather's estate, not fitted for the irrigated agricultural operations of the district.

Watsonville was and is the business center of a fertile farming region, devoted to large-scale production of apples, lettuce, artichokes, and other truck crops. Large amounts of agricultural labor were needed, but local housing facilities for them and other low-income workers were deplorable. Many, for lack of more reasonably priced accommodations, were living in shabby tourist cabins for which they were paying $5 a week.

FIRST GROUP OF DWELLINGS

A 13-acre tract owned by the Porter family was divided into 5 plots of 2 acres each and 1 of 3 acres. As no local banker was willing to finance the scheme, the brothers signed a note for the entire obligation. To carry out the project, a new company (Pioneer Homes, Inc.) was formed. FHA insurance was obtained under Title I of the National Housing Act, under which no down payment was required.

The land was sold to the families at $200 an acre. The house was a structure, 24 by 24 feet, divided into four rooms—living room, two bedrooms, and kitchen. It could be built for about $300. Running water was the only modern convenience provided in this first group. Building materials and tools for this and later groups were obtained through the building supply company of one of the brothers. It was agreed that the men of the families would undertake to provide whatever outbuildings were needed. The total obligation assumed by the tenant was therefore about $700. As the men contributed their labor, by the time the house was completed the family already had an equity of 25 to 35 percent. The remainder of the obligation was to be paid off in 5 to 7 years, in monthly payments ranging from $10 to $15 per month.

PROCEDURES FOR LATER GROUPS

As the plan became known, more applications were received than the sponsors could accommodate. A second group of dwellings was undertaken, on a tract a short distance from town, lying between the county road and the main railroad line between San Francisco and Los Angeles. As, normally, 53 trains a day pass over this route (more during wartime), the sponsors thought this would be a drawback. To their surprise, the plots nearest the railroad were spoken for first; the people liked to hear the trains going through.

---

[1] John and Tom Porter.

These and succeeding homes were built under Title II of the Housing Act (as amended), which required a down payment of 10 percent, but allowed the purchaser to make this payment in labor. The later dwellings had more modern conveniences and cost considerably more than the first group, but embodied the same self-help principle, and the purchaser had as long as 15 years in which to pay off the mortgage loan.

Altogether, some 70 houses were built in Watsonville, 24 in San Jose, and 19 in Stockton, on land totaling about 400 acres. The plan was aimed to care for low-income families for which no housing (within their means to purchase) was available, and for which none was being provided. They included families of agricultural workers (local and migratory), mechanics, artisans, low-paid clerks, etc. Of the first 37 families provided for, only 4 earned as much as $1,200 a year, 7 earned between $600 and $800, and 4 had an income of less than $600 per year. For the first 6 families the average cost, as noted, was about $700; this did not include the value of the man's contribution in labor. For the $1,200 income group the average cost was about $1,360, and for the lower income groups the average was about $950. For these houses the monthly payments per house ranged from $10.32 to $19.89.

In this unorthodox proceeding, in which the purchasers were penniless and had no initial cash stake, the sponsors counted on their self-interest. The brothers felt that the prospect of permanent ownership of a well-built house which the families could obtain for monthly payments smaller than they had been paying for inferior rented quarters would be sufficient incentive to make them "stick." That they were justified in this belief was indicated by the fact that at the end of the first year not one of the first 37 families housed was in arrears; during the first 2-year period only one family was unable to keep up its payments.

SELF-HELP FEATURES AND PROCEDURES

This plan did not embody the Rochdale principle of cooperative ownership; here each family purchased its own home outright. Neither did the plan utilize the exchange of labor which was the principal feature in the Iona and Penn-Craft projects. In Watsonville, each man worked only on his own house.

A family accepted for participation, in Watsonville, was given a choice of house plans within price limitations varying according to its income. The required family equity (in contributed labor) would be 10 percent of the purchase price (land and house) plus closing charges. The man would be shown a cost sheet giving, in the form of "subcontracts," various processes open to him to perform if he was qualified to do so. These were so designed that even an unskilled worker would be able to acquire his 10-percent labor equity; a man with some skill would acquire considerably more.

For each of the processes performed he would be credited with an equivalent value, based on the records of similar work at union rates. The "subcontracts" covered such work as clearing and leveling the land, shoveling, excavating for septic tank and for 45 feet of drain, digging for the foundation, pouring concrete, laying the subfloor and the sheathing for the roof, certain inside carpentry, some interior and exterior painting, etc. The early experience demonstrated the need of trained supervision and this was supplied in the later dwellings.

Local unions cooperated by relaxing their restrictions, to allow a qualified person to perform any work on his own home, in order to establish his labor equity. Union cards were required only for work requiring inspection (such as plumbing and electric wiring). In San Jose the plumbers' union permitted the home owner to serve as plumber's helper on part of the plumbing job; painting was allowed only on condition that it be started and finished by union labor.

Problems, of course, arose. In some cases the labor contribution lagged because paid employment left the home owner little time for work at home. Some of these families were permitted to move into their unfinished houses and to complete their labor contribution later. In other cases, the other extreme was noted; men became so interested in building their new houses that they neglected paid jobs, even to the extent of family privation. The sponsors therefore discouraged any construction work that interfered with cash employment.

In some of the last houses built under the plan, before the war stopped private building, houses were erected on plots of city-lot size. In the others, enough land went with the house to permit a good deal of subsistence gardening, as well as the keeping of chickens, a cow, and even a pig or two in some cases. One man specialized in berries and cleared some $1,200 in 1945 on this crop alone. Another, a former Alaskan "sourdough," made his place almost self-sustaining; this became his vocation, and he took paid work only in amounts sufficient to meet expenses that had to be paid in cash.

Chapter V.—Other Joint Housing Projects

Sponsored by Cooperative Housing Associations

CRESTWOOD COMMUNITY, MADISON (WIS.)

Crestwood is the name of the housing development sponsored by the Wisconsin Cooperative Housing Association, in Madison.

The original group that planned the housing project consisted of persons employed in the various State offices. Through their organization, the Wisconsin State Employees' Association, the first steps were taken in 1936. Later, that association gave way to the housing association proper. Present membership includes not only State employees but also Federal employees, members of the State university faculty, a few local businessmen, and some returned veterans.

Actual construction of the houses did not begin until 1938. In the interval, a tract of 75 acres of land (space for 200 dwellings) was acquired in a convenient suburb, and plans were drawn up for a large-scale development of houses of harmonizing architecture with the understanding that all houses would be owned by the association and leased to the individual members according to accepted cooperative standards.

Long negotiations with the Federal Housing Administration, from which it was desired to obtain loan insurance, resulted in the association's changing its original plan and providing for individual ownership of both lots and houses. This long delay also entailed considerable loss to the association, in preparation and scrapping of plans and in decrease of members as they lost patience and interest. Finally the project plans, covering 20 houses, were approved by FHA, and construction of the first house began in August 1938.

Community Lay-Out

By taking over the entire tract, the association was able to plan in advance the lay-out of a whole community. In this work the association was fortunate in having the assistance of a member with long experience in land utilization. Under his guidance, the plotting of the tract was carried out after a topographical survey had been made, to insure the use of all the natural features to the best advantage.

The whole tract (about half a mile long and quarter of a mile wide) forms a natural amphitheater, with the land sloping up, first gently, then more steeply, to the south, west, and north. The elevation at the highest point is about 1,000 feet above sea level, representing a rise of about 100 feet from the lowest point of the "bowl." The to of the slope is thickly wooded (hence the name "Crestwood") and it is planned to leave this as community land for everyone to enjoy.

A broad avenue, named for the land-utilization adviser (who was the first president of the association), curves through the tract at the edge of the central bowl, and from this avenue dead-end streets run up toward the woods, providing quiet as well as safety from traffic. The wooded slope affords shelter from the north winds and shade in the afternoon. The slight pitch of the streets (which have center drainage) helps to keep the streets free from rain and snow. A narrow strip of community land also runs down between each two cul-de-sacs. In the section that has been developed, one of the strips contains a fully equipped playground, with a supervisor in charge during the summer months. Here also a skating rink is maintained in the winter. In the next park strip, which has a 40-foot drop, other winter sports, such as skiing and tobogganing, are planned. Altogether, about 20 percent of the entire tract is left as community land, title to this area being held by the cooperative association.

In the lowest part of the bowl, near the center, lies an area with rich alluvial soil, which is used for home gardens. Each member is free to utilize a section of this area. In the garden area the association also maintains a tree and shrub nursery with over 6,000 plants, buying these when very small and raising them until they reach usable size. These products are available at cost.

Crestwood is situated on the outskirts of Madison, 5 miles from the State capitol. It is served by a bus line, and members can reach the city in 10 to 15 minutes' ride. There is a grade school at the edge of the settlement. A shopping center, providing varied services, is situated about three-fourths of a mile distant.

Financing of Community Services

The association was incorporated for $100,000 of stock, half common and half preferred, at $50 per share. The non-interest-bearing common stock, of which each member had to have 3 shares, went as payment for the land.

When the association purchased the tract, electricity was available, but there was no water supply and the metropolitan sewer system ended a mile away. Both water and sewer, therefore, had to be furnished by the organization. The proceeds from the preferred stock were used to help finance the installation of the water and sewer system and each member was required to purchase a minimum of 6 shares. Bonds totaling $7,000 were also issued.

A 350-foot well furnished the water, the pumping machinery being housed in a neat station.

The association organized a sanitary district to sponsor the installation of the sewer, turned over to it the sum of $11,000 collected in preferred stock,[1] and received in turn 30-year assessment bonds paying 5 percent interest. The money was used to build a mile-long installation, connecting with the Metropolitan Sewer District trunk sewer, and to lay sewers in the streets of the subdivision. This connection will be controlled by the association for 30 years, during which period, if other subdivisions wish to use the sewer, a portion of the original cost must be assumed by them to retire the bonds held by the Cooperative Housing Association.

The surfacing of the streets was done by the township, but the previous leveling of the street space and the razing of the farm buildings originally on the place were done by the association and cost about $2,500.

When the association has completed development of all the 200 houses that can be accommodated on the land, it will have received more than $100,000 for its stock and land. The difference between actual outlay and this figure represents the association's "potential net earnings," which may be distributed to the members in the proportion that their outlay has borne to the total or may be used for further community development, as the members decide.

Cost to Individual Member

In order to insure that all the members shall be "active," the bylaws specify that no person shall be admitted unless he "executes and files with the association a written statement that he intends to participate in the cooperative housing program of the association and to make his residence in the community * * * as soon as reasonably practicable and feasible."

Each person accepted is required to subscribe for 3 shares of common stock at $50 per share (to apply as part payment on the lot selected). These shares may be paid for in installments, but if so a promissory note or other evidence of indebtedness must be given, the voting privilege being extended after at least $50 is paid in.

Having been admitted to participation, the member is entitled to select a lot. Selection is by "priority of the dates of stock subscription." The lots average 60 by 120 feet. The basic price per lot is $450, but the more desirable locations run higher. In fixing the price, certain "desirability" factors (seclusion, view, and environment) were taken into consideration, each factor carrying an extra charge of $50. For the less desirable lots, the $450 covers the total cost of lot and stock; for the most desirable the cost runs as high as $600, and one lot.

---

[1] By the end of 1946, it was reported, most of this preferred stock had already been retired.

high on the hill road, was priced at $700. The average cost of the lots already bought is about $500. This represents a considerable saving from the current local prices for fully serviced real estate, and it is possible that the price may eventually be still further reduced by refunds, after the entire development is completed and all costs are computed.

When the member has completed payment for his stock, plus any "desirability" factors, he receives title to his land. He is then ready to negotiate for a dwelling. Ordinarily,[2] from this point onward, he acts for himself. The construction of his house is his responsibility, except that he may utilize one of the association's floor plans drawn for the association under the original scheme of collective ownership.

Before construction may be undertaken, the plan chosen must be submitted to an architectural committee, in order to insure that the style will not clash with that of the rest of the houses. The total cost may not fall below $3,000. The member must also furnish evidence of eligibility for FHA insurance or of ability to finance construction without such insurance.

Some of the members have reduced costs by doing some of the work themselves. Thus, one member who was an electrician wired his own house. He and several of the other members did their own painting.

Most of the financing was done through two local lending agencies, with FHA insurance. The member's monthly expense includes amortization payment, interest, and certain community charges. These latter include water rent (proportioned to use, minimum $17 per year), and 25 cents per month for garbage collection. The assessment for sewer is incorporated in the taxes and averages $2 to $3 per year.

A member desiring to withdraw has the right to sell his house, provided the purchaser is acceptable to the association, and provided his stock is transferred to the purchaser. However, he must give the association the first option to buy.

Types of Dwellings

The houses exhibit a variety of architecture and of material. One of the larger houses has a field-stone front. Several are of wood, being either painted or stained, but perhaps the greatest number are constructed of 8-inch concrete blocks with cores filled with waylite. In architectural design, the dwellings range from the Cape Cod cottage to the most modern style. In cost, they have ranged from $3,500 to $6,500; before the war the association tried to discourage the building of houses costing more than $5,000.

All the Crestwood houses are of the one-family type, consisting of a kitchen, dining room or breakfast nook, bathroom, living room, and

---

[2] But see p. 60.

(with one exception) two or three bedrooms; the exception is a four-bedroom house. They are equipped with oil burners, and a number have fireplaces as well. All but two have built-in garage. A recreation room is also a feature commonly found. Each house has standard plumbing and electrical equipment, and about half the houses are of fireproof construction.

Practically none of the dwellings faces squarely any of the cardinal points of the compass. Generally the house is turned slightly, so that each room receives sunlight at some time of day.

Present Status of Association

Up to November 1946, only one division had been opened, and construction had taken place on only the three northernmost cul-de-sacs and the outer (hill) road. In that section, 38 dwellings had been completed before war conditions halted private building. During the war period, all but 2 of the vacant lots remaining were sold to new members. However, as most of these were not veterans and could therefore not obtain priorities, only 6 houses (all those of veterans) have been erected since the resumption of building.

An additional street was opened for development in the autumn of 1946 and one house had been begun by mid-November 1946. Another street will be opened in the summer of 1947. Installation of sewer and water facilities for this additional land was financed by the sale of 4-percent 10-year callable bonds. This bond issue was offered to members of the housing cooperative and is reported to have been oversubscribed 75 percent. The new facilities are part of the Crestwood Sanitary District, the commissioners of which are three member-residents of Crestwood. The sanitary district now also includes the adjoining section of Glen Oak. Several parcels of unimproved land in that section have been bought by the Wisconsin Cooperative Housing Association; its lots there are being sold at prices ranging from $150 to $300 each.

In 1940, using funds loaned at 2 percent by an anonymous lender, the association undertook a new step—the building, itself, of dwellings at cost for prospective members who do not have the time or inclination to proceed individually. Three such houses had been erected before the imposition of wartime building restrictions. In such cases the procedure is as follows: The new member is required to purchase the lot, on the usual basis or, possibly, may even be accepted on a rental basis, the accrual over expenses being used to finance the family membership. When the householder has paid for his lot he makes the usual arrangements with a lending agency and the FHA. The loan from the lender is used to pay the housing association and the money thus released is used in the construction of another house on the same basis.

Extent of Cooperative Enterprise

The achievements of the cooperative association have been the following: (1) The purchase and plotting of the tract, (2) the financing and installation of a water and sewer system, (3) the creation of a sanitary district, (4) the furnishing of architectural service, (5) the supplying of title insurance for members, and (6) the building of a small number of houses itself. As noted, all but 3 of the houses were constructed by individual contract and the association has no control over them except to pass upon the general style of architecture, to see that the cost does not fall below the minimum of $3,000, and to pass upon the acceptability of purchasers. A withdrawing member must give 60 days' notice and give the association the first option to buy, at either par or book value (if the latter is less). Should the association not exercise its option, no controls are imposed as to sale price. During the life of the association several dwellings have been sold, but none, it is said, "out of line with relative costs of building." Two houses for which disproportionate prices were asked remained unsold "because members of the community do not care to have their friends buy at the prices asked by the owners."[3]

Each member has one vote only, regardless of his investment, and no proxy voting is allowed.

In November 1946 the association was negotiating with the U. S. Weather Bureau for an arrangement whereby the latter would install equipment for the measurement of south-exposure solar radiation, to determine its value in the heating of houses. Some use of this principle has already been made in Crestwood; the first president of the association reports that its use has made possible the heating of his 6-room house, with oil heat, for less than $75 per year.

Other cooperative activities.—Many of the electric fixtures were bought through one of the members (a dealer in such appliances), at a saving of about 25 percent; stove, refrigerator, and water heater together cost only $250. Some furniture was also purchased collectively, at a saving, by special arrangement. Cooperative purchase of eggs, poultry, etc., is also carried on. The housewives alternate in acting as agent, taking the orders and receiving and apportioning the goods.

A large proportion of the residents are members of the cooperatives of the city, these including a gasoline service station and store and an association giving dry-cleaning service. As most of the members work in town and thus have to go in every day, these associations can fill their wants conveniently. The fuel oil for all of the furnaces is supplied by the petroleum cooperative.

---

[3] **Letter to Bureau of Labor Statistics from John S. Bordner, October 1, 1945.**

ST. PAUL (MINN.) HOUSING PROJECT

The Cooperative Housing Association of St. Paul was formed in September 1939. Construction began in July 1940.

The association, composed of members of credit unions of Federal, State, and city civil-service employees, purchased from the State 72 lots which had reverted because of nonpayment of taxes. On this property, gas, electricity, water, and sewer had already been installed as well as streets. Only curb and sidewalks were lacking.

The land on which the project was developed lay on an elevation at the northeastern edge of St. Paul, about 3 miles from the center of the town. A grade school was about 3 blocks away and a high school about a mile distant. Four blocks from the project was a bus line, accepting token fares and offering transfer privileges.

Financing and Procedures

The association had no capital stock. As each member joined the association he paid a $5 membership fee and agreed to buy a lot and construct a house on it. The project was financed through the sale of lots to the members, by loans from the St. Paul chapter of the Minnesota Credit Union League, and FHA insurance.

The lots, with an average frontage of 40 feet, were replotted into 48 lots with a frontage of 60 feet. The depth varied from 112 to 126 feet. There was also a 20-foot alley. The cost to the association was $75 per 40-foot lot (or $112 on the replotted basis); the price to the member was $350. The difference was used for association expenses, any surplus being returned in patronage refunds.

Minnesota has a strong credit-union movement, with large accumulations of funds. As the State act permits credit unions to make real-estate loans, the central credit-union organization qualified as an FHA lending agency and proceeded to make mortgage loans on a 25-year basis to finance the individual dwellings. FHA insurance was then applied for, and in most cases the maximum FHA insurance of 90 percent of the appraised value was granted.

With one exception,[4] a single architect served the whole group of owners, receiving as his fee 3 percent on the total cost.

Likewise, one contractor had charge of construction of all but one of the houses.[4] With this contractor, the association had a contract by which he guaranteed his bid on each house; if the final cost exceeded this amount he was to bear the extra expense. If there was a saving, it had to be returned to the member, to increase his equity in the property.[5] His bid was based upon cost of construction (materials and labor) plus architect's fee, plus a $100 "cushion." The contractor's compensation consisted of a flat fee of $250 per house.

---

[4] The exception was a member, himself an architect, who was allowed to draw his own plans and supervise construction of his house.

As the association's charter authorized it to act as contractor, the selection of materials and the letting of contracts for them were done by its board of directors. In this the association tried to make use of all possible sources of assistance and information, in order to insure the best quality. Results of tests by recognized testing agencies were used, and valuable help was received from the State university.

Prefabricated materials and standard equipment were used whereever possible. Thus, although a few of the houses were plastered, the majority were finished with tinted Upson board—a prefabricated material that comes in sheets 8 by 16 feet (doing away with joints that might let in drafts), the space between the walls being filled with 2 inches of glass wool, vapor sealed. Heavy plywood was used in subfloors and in outside wall and roof sheathing; this construction was cheaper and made for a more rigid house, with less air leakage. A factory-finished oak flooring was used in all houses.

As the dwellings were constructed in groups of about 10 and the contracts let on the basis of 25 houses, it was possible to do quantity purchasing, such as carlot quantities of lumber and plywood, and gross orders of standard plumbing fixtures, window glass, and other requirements. This resulted in substantial savings. On the lighting fixtures and refrigerators about 40 percent was thus saved, and nearly 50 percent saving was realized on some furniture bought jointly.

Again, by building a number of houses simultaneously, efficient use of labor was possible, each crew of workers performing the same task from house to house and being succeeded by the workers performing the next process in construction.

Only persons belonging to some St. Paul credit union [6] were accepted for membership. Prospective members were also required to supply information on their employment, income, number of dependents, and financial obligations, in order to determine their eligibility from a financial standpoint. Members joining the association had to purchase a lot, at a price of $350; this sum, which included the $5 membership fee, represented a considerable part of the 10-percent equity the member must have to obtain FHA insurance.

The cost of the individual house depended upon the size and style selected, and upon the quality of the equipment that went into it. If the member desired extra-fine hardwood flooring, or a deluxe refrigerator, these of course brought up the cost. However, as the members for whom the dwellings were built all had modest incomes (averaging less than $200 per month in 1940), the houses were also of moderate-priced styles. The buildings ranged from the 2-bedroom, living room, kitchen (with dinette), and bathroom dwelling to a 7-room house with 3 bedrooms, living room, kitchen, dining room, and bathroom. All the houses were of frame construction. Many had fireplaces, a few had recreation rooms, and nearly all had garages (built separately from the house).

---

[5] An FHA regulation forbade the return of such savings in cash; the amount must be used to reduce the mortgage.

[6] As credit unions are allowed to make loans only to members.

The maximum bid cost ranged from $3,750 to $5,400. Savings (estimated at about $100 per house) were returned to the individual members in the proportion that the contract price of their house bore to the total cost of all the houses. This prorated sum was applied to the reduction of the member's mortgage. The "profit" which the association made on the lot was to be returned to the members, after deduction of expenses.

For these houses the average cost to the member was about $35 per month, with a maximum of about $40. This sum included amortization, interest (4½ percent, plus ½ percent for FHA insurance), and taxes. These payments began 30 days after the member moved into his dwelling. No other down payment than the value of the lot was required from the member, if his house cost $3,500 or less. Above that amount he had to pay down 10 percent of the excess over $3,500.

The association's officers emphasized that the cost to the member was about what he would have paid at that time to a private builder for the same style and size of house. However, under the association's plan there was no profit for anyone, as officers served without pay, and architects and contractors were on a fee basis. All subcontracts and material contracts were subject to approval by the board, which likewise controlled all payments. The entire cost of the project, therefore, was under the control of the association. The officials were convinced that, because of economies effected by carlot purchases, by standardization (as of window and door openings), and by systematizing the use of labor, the quality obtained in both materials and workmanship was considerably above that which would be obtained in houses of the same price under separate contracts. In other words, the association made available to a moderate-income group, for amounts they could afford to pay, dwellings of a quality that would otherwise be out of their reach.

Cooperative Activities

The activities of the cooperative association in this case included the purchase of the land, the engagement of architect and contractor, and the letting of bids for materials and equipment. It held title to the individual plots until sold, then turned them over to the purchaser. The latter then negotiated with the association's architect and contractor for the kind of house desired, and when he moved into it the association's responsibility ended.

In the purchase of refrigerators, electrical equipment, and furniture, the association patronized the two nearest cooperative wholesale associations. In houses in which Upson board was used for interior wall finish, the walls were tinted with a casein wash made by a cooperative creamery association in Minneapolis.

There are in St. Paul various local cooperative enterprises—a store association, gasoline cooperative, etc.—and a large proportion of the original members were also members of these. Most of the houses were equipped with oil-burning furnaces, and the fuel oil for these was obtained from the petroleum cooperative. Cooperative life and automobile insurance was also available.

In the association each member had one vote. He owned and had title to his individual dwelling, but if he desired to sell his house within the first 5 years the purchaser had to be acceptable to the association. If not, he had to give the association the right to purchase it for what it cost him or at an amount set by an arbitration committee. Apparently these provisions were not enforced and, as prices rose, "speculation was rampant." Houses were sold three or four times, at continuously rising levels. The association is now dormant and plans no further activities. A recent report from the former president expresses the opinion that, from the cooperative point of view, "our efforts were somewhat of a failure."

MINNEAPOLIS (MINN.) HOUSING PROJECT

The Cooperative Housing Association of Minneapolis was started in February 1940. Construction was begun on the first house in September 1940.

As in St. Paul, the association bought the land for its project from the State, paying for it at the rate of one-third of the tax assessment which was delinquent. Some 59 lots in 5 different adjoining blocks in northeast Minneapolis were acquired in this way. The lots were 40 by 125 feet, but were replotted into lots 50 and 60 feet wide. The average cost to the association was $2.50 per front foot, but the land was sold to the member at $7.50 per foot (appraised FHA value). All of the improvements—water, sewer, gas, electricity, and streets—were already in, but the association was required to pay the regular assessments therefor. A considerable part of the difference between the cost to the association and the sale price to the members went to meet these assessments. The association sued the State for refund, contending that under the law the price of tax-reversion land includes utilities. Its position was upheld by the Minnesota Supreme Court, resulting in the recovery of $4,500.

The land acquired was about 4 miles from the center of town, with a grade school about in the center of the tract, so that the distance traversed by the children was in no case more than 2½ city blocks. The nearest high school was 1½ miles away. Stores were within easy walking distance. The streetcar line was 6 blocks away, but a bus line was extended into the development.

There were, in the original group of interested members, 45 persons. During the interval in which financing negotiations were carried on, 3 members lost patience and withdrew, a fourth lost his net worth by fire, and 10 others were rejected because their incomes were too low to undertake the financial obligations involved. Houses were built for the 31 members remaining and for 56 additional members who joined later—a total of 87 dwellings.

Finances and Procedure

As already indicated, the associate paid for the land an average of $2.50 per front foot and sold it to the members for about $7.50. For corner lots an additional $25 was required.

The architect was hired by the association for a fee amounting to 2 percent of the cost of the houses.

A master contract for the whole group of houses was made with a large contracting firm, by which the latter received a fee amounting to 3½ percent of the total cost of the dwellings (minus the architect's fee), and for which the contractor agreed to manage the construction of all the houses. The company guaranteed to keep the cost of the houses within the amount of the maximum bid, or failing this, to meet the excess cost itself. As an incentive for saving on the cost of construction, the contract provided that 25 percent of the first hundred dollars of any such saving should go to the contractor and the remainder to the owners. The contractor, however, had the privilege of totaling costs for all houses, so that a surplus on one could be used to take care of a deficit on another. The association controlled the purchasing done by the contractor; no purchase could be made or subcontract let without approval by the association's board of directors.

The contract also provided that the work on the houses should be done by union workmen receiving the prevailing union scale of wages, and the contractor agreed to give the carpenters a bonus of 50 percent of their regular hourly rate for every hour of labor saved from the contractor's estimate.

The bid prices on the houses ranged from $4,100 to $6,000. The average or typical house cost about $4,700, or from 28 to 30 cents per cubic foot. All of the houses were of frame construction, and were equipped with all modern improvements, including furnaces using natural gas.

As in St. Paul, considerable reductions in price were obtained by quantity purchases. The officers estimated that at least $200 per house was saved on the cost of materials and equipment. Other savings resulted through the use of the Torrens title (i. e., the taking of title to many lots at once), in attorneys' fees, and in title charges. Whereas the title charge for one lot was $25, when the title covered 3 or more lots the charge averaged only about $7 per lot. Because the association held title to the whole tract, title insurance was unnecessary and the cost of insurance was therefore saved. Lower tax rates were also possible because of the larger valuation covered by the single tax title.

Cost to Individual Member

Each member was required to furnish information regarding his financial status and to pay a membership fee of $5. He selected his lot in the order in which he came into the association. According to the size of the lot chosen, this cost ranged from $300 to $450. The average was about $375.

Although this constituted most of the 10-percent equity the member had to have in order to qualify for FHA insurance, he might also have to furnish an additional amount varying with the value of his house. Thus, a 90-percent guaranty on a $5,000 house would cover a maximum loan of $4,500. The difference between the two sums—$500—had to be made up by the member. The cost of his lot (average $375) covered most of it, but the remaining $125 and an estimated $50 to $75 for "closing costs" had to be raised by the member. The immediate investment required from the member therefore amounted to about $425 to $600, depending on the cost of his house and on FHA appraisal of its value in the light of style and construction elements which together constitute the "marketability."

The member's average monthly payment (amortization, interest, loan insurance, and fire insurance) amounted to about $24.50 a month on a $4,600 house with a 25-year mortgage. Taxes in the neighborhood, on houses of these values, averaged another $8 per month. The average income of the whole group of members in 1940 was about $1,700 to $1,800.

Sponsored by Labor Organizations

CARL MACKLEY APARTMENTS, PHILADELPHIA (PA.)

The Carl Mackley Apartments,[7] Philadelphia, constituted the first housing project undertaken in 1934 by the Public Works Administration when it was established after the passage of the National Industrial Recovery Act. The project was planned and sponsored by the American Federation of Hosiery Workers (CIO), with the purpose of providing suitable housing for its members, many of whom were living under substandard conditions.

The union exchanged a piece of land owned by it in the downtown section for one of 4½ acres (valued at $85,000) in the Frankford district. A 35-year, 4-percent Federal loan of $1,039,000 was obtained, and additional funds were supplied by the union, by a public-spirited Friend, and by other individuals. A limited-dividend corporation, the Juniata Park Housing Corporation, was formed which supervised the construction and still holds ownership and management of the project.

Housing and Community Facilities

Housing facilities.—The apartments consist of four rectangular buildings of terra-cotta brick and fireproof construction. The whole project covers an entire city block, but the buildings occupy only a third of the space. The rest consists of lawns and recreational space. The buildings are three stories high and, as they run north and south, practically every room has sunlight at some time of the day. No apartment is more than two rooms deep and each one has at least two exposures (those of largest size have three exposures).

The 284 apartments range in size from 2½ to 5 rooms. The monthly rentals range as follows: A 2½-room apartment of living room, bedroom, pullman kitchen (i. e., 2-burner electric plate, cupboard, and sink, closed off from the living room by folding doors), and bathroom (with shower only) rents for $29.00: a 2½-room apartment with kitchenette (i. e., space for table and chairs, in addition to facilities noted above) and bathroom with tub, for $33.50; a 3-room apartment, with full-sized kitchen, for $38.00: a 4-room apartment for $42.00 if on the third floor, and for $43.00 if on the second; a 4-room apartment with a bay window, $46.00; and a 5-room apartment (each with shower as well as tub), $48.00–$51.00, depending on its location. These rentals include heat, water, and electricity. Electric stoves are furnished, but tenants have to provide their own refrigerators. All apartments on the second and third floors have a porch which they share with the neighboring apartment. Waste disposal is through an incinerator in their common hallway. Ample closet space is provided.

---

[7] Named for a young hosiery worker who was killed during a strike in 1931; several plaques throughout the buildings commemorate other fatalities in the same strike.

Community facilities.—On the roof of each building is a laundry with windows on both sides; equipped with stationary tubs, electric washers, ironing boards, and electric dryers (used in bad weather). Drying space is provided on the roof outside the laundry. There is no charge for the facilities or the electric current used here. By agreement among the tenants of the building, each family is allotted laundry-use time each week.

Other community facilities include an auditorium where social events and other meetings are held, 59 heated garages renting for $5 per month each,[8] and a large swimming pool. The pool is used by both residents of the project and persons living in the neighborhood, for a nominal fee, but outsiders pay at a slightly higher rate.

Selection of Residents

When vacancies occur, preference is given to union hosiery workers, other unionized industrial workers, and other industrial workers, in the order named. Although textile workers form the largest group in the present population of the houses, many other occupations are represented, including both manual and "white collar" workers. Families with children are preferred. The general requirement is that the monthly family income should not be less than 3 times nor more than 5 times the monthly rent of the apartment desired.

In this project the resident never becomes the owner of either his apartment or of equivalent stock in the association. For as long as he remains in the project he is a renter only.

One apartment is given over to a nursery school, staffed by three teachers and a cook, all hired by the housing corporation. Owing to the limited space, the present capacity of the school is 45 pupils. The facilities are available to both residents and outsiders, with preference to the former. Here, for a fee of $1.25 per week (5 days) the children receive instruction in such subjects as drawing, modeling, block building, and nature study, have supervised rest and play periods, and (if they are all-day pupils) lunch as well. Each child is examined every day by one of three trained nurses who live in the project and donate their services. Naturally with the low fee charged, the school is not self-supporting. In 1945, only about 56 percent of its income came from fees. The housing corporation provided quarters, heat, light, and water, and the remainder was contributed by local hosiery workers' unions and interested individuals or was raised from the proceeds of benefits, dances, etc., given by the residents. It is hoped that the nursery can be expanded when building materials become available.

---

[8] A parking lot, formerly operated, had to be given up for the construction of a number of dwellings by a private builder.

Cooperative Activities

Although the first resident did not move in until early in 1935 and the last one not until October, before the end of the year a credit union had been formed. Beginning with only $28 in share capital, at the end of the first year (by March 1937) the association had increased its capital to $5,496, had 200 members, and had outstanding loans amounting to $5,307. Its operations have been continuously successful, and for 1946 it paid a 3-percent stock dividend on the year's operations. Membership and loans are restricted to residents of the Carl Mackley houses, and the business is all transacted on Friday evenings. All help is volunteered, with the exception that the secretary receives a small honorarium.

Out of a small buying club, started shortly after the credit union commenced operations, grew the Juniata Consumers' Cooperative Association. At the time that it opened its store (March 1937) it was the only cooperative store in Philadelphia that was open full time. The store handles both meat and groceries, and has steadily increased its business. By October 1946 it had reached nearly $2,200 per week. Its present problem is that of space; although it has outgrown its quarters no additional space in the project is available. Membership (now about 130) is open to both residents and nonresidents. The association is affiliated with the Philadelphia Cooperative Federation as well as Eastern Cooperative League and Wholesale.

Administration and Finances

The Juniata Park Housing Corporation which is the owner of the property has a board of five directors, one of whom is appointed by the Federal Government. Actual day-to-day management and operation of the houses is carried on by a paid manager and his staff.

The project has suffered from the effects of two early financial assumptions that proved to be mistaken: (1) Largely because of the required use of WPA labor, the total cost of construction proved to be some $200,000 more than had been anticipated. Because of this, certain planned features had to be either eliminated or curtailed. Thus, the auditorium was left without equipment, and the refrigerators which were intended as part of the provided equipment had to be furnished by the residents. (2) At the time the project was started, it was expected that legislation would provide tax exemption for a certain period (as is the case under the New York housing law for limited-dividend corporations). Rentals were set accordingly.

For 3 years, expecting such legislation, the corporation paid no real-estate taxes. At the end of that time, taxes were suddenly demanded for the whole 3-year period—amounting to some $20,000 on an assessed valuation of $660,000. The corporation has never quite recovered from the financial shock thus administered. It has kept up its interest payments on its Government loan, and part of its amortization. Neither the union (which, apart from the Government, is the heaviest stockholder in the corporation) nor any of the other investors has received a penny of interest. An application for a moderate increase in the rents (which are below the prevailing local level, even without considering the unusual facilities provided) was recently filed with OPA. Such an increase would enable the corporation to regain some of its lost ground.

STONEWALL HEIGHTS, FRONT ROYAL (VA.)

The Local Housing Situation

Front Royal lies at the northern end of scenic Skyline Drive in Virginia, in a valley in the Blue Ridge Mountains. A large viscose plant, manufacturing heavy-duty auto-tire cord, is the main industry and employs about 3,500 workers.[9]

The already acute housing situation was aggravated when, at the most critical stage of the war, an extension of the plant was undertaken, doubling its facilities and calling for many additional workers. So great was the housing shortage that workers had to live as far as 25–40 miles away and drive back and forth each day. A trailer camp, installed for the construction workers who were building the new plant, was later made available for the textile workers. Several hundred dwellings were erected with Lanham Act funds, and a private contractor was given priorities for some 300 FHA-financed houses.

Even these failed to meet the need. Also, the union felt not only that the price ceilings (about $8,000 purchase price and about $50 per month rental) were above the level that its members could afford to pay, but that the houses themselves were too small for the workers' families, unsuitably planned, and lacking in storage space.

Late in 1944 the local union (No. 371) formed a housing committee to see what could be done. Its first step was the construction of a sample house. This was undertaken with the idea of ascertaining the price at which a well-constructed house, designed to meet the needs of the members' families, could be built. A tentative goal of $5,000 for house and lot was set, but the final actual cost was $7,800. In the belief that a considerable element in this high cost was the fact of its being a single unit, the union decided to undertake a larger-scale house-construction project.

---

[9] Of these, the 3,000 who are production workers are practically all members of the textile workers' union.

About this time 57 acres of farm land on high, rolling terrain, overlooking Front Royal and with a beautiful outlook toward the mountains on all sides, came on the market for $25,000. With funds contributed by union members and friends, this land was purchased and the plans for a whole new community, Stonewall Heights, were drawn. The plans provided for 158 dwellings, with space reserved for recreational and community facilities. For practical and financial reasons a group of only 50 units was actually undertaken.

Problems Encountered

An unusual number of difficulties was encountered. The first was the inability of the local union to hold title to real estate, under the Virginia law. As a result of union efforts an amendment was obtained which removed this disability.

In the beginning the formation of a cooperative association, which would hold title to the property and carry out the project, was considered, but was found not to be legally feasible in Virginia. A regular stock corporation, the Old Dominion Housing Corporation, was therefore formed, the officers of which were on the staff of the Textile Workers of America or members of the Front Royal local union. Because of inability to obtain a suitable arrangement with a private contractor, the Old Dominion Housing Corporation had also to act as its own contractor.

Several months elapsed before the approval of the local planning commission could be obtained. As its approval was conditioned on the widening of the road leading into the property, the corporation had to buy strips of land on either side of the road. Delays ensued because some of the owners were away in war service or there were judgments or mortgages against the property.

As the farm land purchased for the site lay outside the corporate limits of Front Royal, in order to obtain access to municipal water and sewer facilities and to gas and electricity, the corporation had to build connections—an operation that it is estimated added at least $1,000 to the cost of each house. Further, the project was carried out in a time of unprecedented scarcities and one of erratic price rises. During the 12 months in which the project was under way, prices of materials almost doubled. Bricks rose in price from $19 per thousand to $34, and lumber which cost $57 per thousand feet in June 1945 had risen to $78 by April 1946 and was still rising. Other lags, resulting from an unusually severe winter, delayed outside operations and caused difficulties in obtaining supplies and equipment.

All of these situations entailed what seemed like interminable delays, and it was not until June 1945 that ground was actually broken and the construction of the first house was begun.

Not the least of the many difficulties was the problem of financing. Several of the leaders contributed all their savings, local unionists advanced funds, the local unions in Roanoke, Parkersburg, and Front Royal made loans out of the union treasuries, and the national union also helped. Finally a loan was made through a local bank. Nevertheless, funds were barely sufficient to cover operations.

In addition, the project had to contend with local hostility from certain sources, with suspicion as to the motives of the leaders, and with rumors that the whole project was "going broke." Not only did these things make the going harder, but they necessitated the waste of much valuable time and effort to overcome them.

However, by August 1946 all 50 houses were practically complete and a number were occupied, with families moving in each day.

Conditions of Sale, and Price of Dwellings

In order to regulate the sale of the houses, a seniority system was adopted and a registration fee of $10 was charged. Applicants were given their choice of houses in the order of their registration for purchase.

The first few houses completed were built for $5,500 and $6,000, the next 30 cost nearly $7,000 each, and the final lot about $8,000. No profit was involved at any stage. Regarding the nonprofit aspect, a report to the union members made the following statement:

> The architect-engineer was paid on a per unit fee basis for his architectural and engineering services. In this case, his fee was lower than ordinarily charged for such work. The two people who actually ran the job—directed the construction and managed the business on the site—were paid a regular weekly wage, about the same as paid on any job of the kind. The attorney, who also handled all the business details of the job, was paid a weekly retainer and certain minimum fees for legal work performed for the corporation. None of the directors drew a dime. None of the 30 or 40 people who loaned money to the corporation were even given interest on his or her money. * * *
>
> A small-town banker in Rockymount, Va., put up the construction loan and the mortgage money. This banker proved to be thoroughly in sympathy with the aims of the union in doing this project and helped the job along in every way he possibly could. This gentleman would want to work with TWUA on similar projects in the future if possible. The fact is that it is very easy to borrow all the money needed from big or little concerns and at banks and insurance companies, for workers' housing, if competent people are hired who will see to it that the plans are properly made and strict business methods adhered to.
>
> It was necessary to pay several thousand dollars of broker's fees for financing and charges in connection with putting this job through which would not have had to be paid if there had been adequate capital to get the job started.

The total costs were averaged and for the whole group of 50 houses the purchase price was set at $6,050.

The purchaser is required to make a down payment of $650 (which includes settlement costs of $114) and monthly payments of $33.68 over a period of about 25 years. It is pointed out that, because of the nonprofit feature of the project, dwellings of comparable size and construction could not be found elsewhere for less than $8,500 to $9,500. Actually, the report made to the union membership notes, the $6,050 charged does not entirely cover the true cost (about $7,800, because of the sharply rising prices). The difference was covered from amounts realized from the sale of surplus land not needed for the project.

The lots average 65 by 130 feet, and the houses themselves are 34.4 by 26 feet. Each house differs slightly in appearance from the others. The construction is of solid masonry throughout, either brick and cinder tile or brick and concrete blocks. Every house has a large living room with fireplace, two bedrooms, bathroom, and kitchen. Each is furnished with a gas or electric range (according to the choice of the purchaser), electric lighting, full basement, laundry tubs, and a hot-air furnace so constructed that it can readily be converted to oil and with ducts that can also be utilized for air conditioning. An unfinished second story provides space for an additional two bedrooms, and some of the early residents soon began work on them.

All streets in the project are to be hard surfaced, with concrete sidewalks. Surfacing of roads and construction of sidewalks was in progress at the time the Bureau's representative was there. Trees and shrubs are to be planted.

As regards the individual purchaser, there were no self-help features involved in this project. The house was delivered to him completed. However, several of the families which had taken possession at the time the project was visited were working on the conversion of the attic space into bedrooms and doing the carpentry, painting, and other work involved, and at least one man was putting in rock wool insulation.

Each purchaser receives title to his dwelling. With a view to checking any tendency toward profit making on the part of the purchaser, the sale contract originally used contained a provision giving the corporation the first right to repurchase if the tenant wished to move away. However, because the corporation actually had no funds with which to carry out this provision, it was useless and was later dropped. By August 1946, one member had already sold his house, realizing a $2,000 profit—a circumstance very disheartening to the leaders who had given so freely of their time in order to insure the nonprofit feature of the project.

Nevertheless, the leaders feel that, aside from its part in alleviating the housing situation, the project was worth while as a demonstration of the possibilities of group action. They emphasize, however, the absolute necessity, in such a project, of responsible, altruistic leadership, and the employment of thoroughly competent technicians.

TULSA (OKLA.) BUILDING-TRADES COUNCIL PROJECT

Early in 1941 the Tulsa Building-Trades Council formed a housing committee. As a result of its recommendations, the various building-trades unions which were members of the council formed a nonprofit corporation in which each took shares of stock. A tract of land was obtained, and arrangements were made whereby persons participating in the plan could take options on plots of their choice. Originally, participation was restricted to members of the sponsoring unions; later any unionist was admitted.

Plans were obtained for houses of the types which would be suitable for the families concerned and contracts were let for five dwellings. It had been planned that the members (building-trades workers) would work on their own houses and be allowed credit therefor on their down payment, at current union rates. However, because of the great amount of construction work entailed by the defense housing program, the men were kept too busy to do so, and all five had to be built in their entirety by the contractor whom the corporation hired. In the end, not one of the houses was bought by building-trades workers, though all the purchasers were unionists.

According to a leader in the project, the purchasers saved about 10 percent because of the nonprofit feature of the plan. He states that the unions expect to revive the scheme again as soon as conditions become favorable.

Other Sponsorship

GARDEN HOMES CO., MILWAUKEE (WIS.)

An experiment carried out in Milwaukee under the leadership of the mayor, some 20 years ago, is of interest here, in that it provided a method of financing probably unique in this country, although it has been fairly common in Europe.

Briefly, the plan provided for participation by cities and counties through their investment in the preferred stock of a housing enterprise. Subscription for such stock was also open to other organizations and to individuals. The preferred stock was retired as the tenant-owners paid for common stock to replace it. The plan involved no public subsidy or expense to the taxpayers, for interest was paid in the meantime.

The original plan contemplated the erection of about 3,500 houses. Actually, only 105 were built, and as far as the Bureau's information goes, no further action has ever been taken. However, although the plan did not materialize on the scale that was contemplated and the cooperative feature of common ownership was dropped, the enabling legislation is still on the Wisconsin statute books,[10] and could be utilized if interest in doing so were present or could be aroused.

Background and Operation of the Project

In 1920, according to the statement of its mayor, "Milwaukee was the most densely populated city in the country. The acute housing shortage was threatening to develop slum conditions, breeding places for disease and crime."[11] Among the various measures examined, for the relief of this situation, was a plan for a city-sponsored housing project. Action was taken under a law that had been passed in the preceding year at the request of the Milwaukee Housing Commission, authorizing the formation of housing corporations on a cooperative basis.[12] Such corporations were permitted two kinds of capital—common stock (to be held only by the tenant-owners, in amounts equal to the value of the premises occupied by them) and preferred stock (to be held by investors). One section of the law authorized the common councils of cities and the county boards of supervisors to subscribe for the preferred stock of such a housing corporation owning land within the limits of the city or county of their jurisdiction.

Under these provisions the Garden Homes Co., of Milwaukee, was formed, under the auspices of the Milwaukee City Housing Commission. The stated purposes of the company were as follows:

> The elimination of speculation in land values.
>
> The economic and adequate planning of streets, sewage, water, lighting, tree planting, and recreation spaces.
>
> The elimination of waste and of private profit in home construction.
>
> The collective ownership of homes by the workers, without the handicap of labor immobility.
>
> The use of legal, technical, and artistic skill for the benefit of Wisconsin's citizens and home owners.[13]

The company's authorized stock was $500,000 ($250,000 common and $250,000 preferred). Shares were $100 each. Preferred stock was to draw interest at the maximum rate (5 percent, cumulative) permitted by the law. Each tenant-member of the corporation was required to subscribe for shares equal to the value of his dwelling.

The city subscribed for $50,000 worth of the preferred stock, and the county took an equal amount. The Association of Commerce[14] and other organizations as well as individuals also invested. Altogether, according to a report by the company to the U. S. Bureau of Labor Statistics, there were 30 holders of preferred stock. Bank loans completed the necessary financing for the $500,000 project.

[11] How Milwaukee is Improving its Housing Conditions, by Daniel W. Hoan. *In* American City (New York), July 1930, p. 136.

[12] Acts of 1919, ch. 402.

[13] Report of Proceedings of Third Congress of The Cooperative League, 1922, p. 104.

[14] This organization is reported to have withdrawn later, undertaking a plan of its own (The New Day in Housing, p. 162).

Voting of both common and preferred shareholders was on the basis of shares held. This concession, it was explained, "was necessary, temporarily, to satisfy the loan investors' prejudices."[13]

A 30-acre tract of land, half a mile outside the city limits (but later incorporated within them), was bought for $29,000. It was divided into plots 60 by 100 feet, with an average price of $700 per lot.

The plan provided for 4-, 5-, and 6-room houses which, it was expected, would cost about $4,500 each (including cost of land). Final cost, for the 105 dwellings that were built, was about $5,000 each (the maximum allowed in the law), but even that price, it was claimed, represented an average saving of "fully $1,500" per house.[15] Economies were reported to have been effected through the wholesale buying of land and materials, through the building of many houses at once, and through the elimination of speculative profit. "The tenant obtains a home, at a rental not higher, and probably less than elsewhere. Although the cost of the house is high, more than the average worker can today afford, yet the present members are obtaining homes which could not possibly be bought at such a price otherwise."[16]

The tenant-owners were required to make a down payment of $500 (about 10 percent of the cost). Monthly payments (covering taxes, insurance, repairs, interest on preferred stock, and amortization on preferred stock and bank loans) averaged $8.50 per room or about $45 for a 5-room house or $50 for one of 6 rooms. The houses were to be paid for in 20 years. Under group insurance taken out by the company, if a member died or became totally disabled before completing payment, the insurance would cover the unpaid amount of his capital stock. His family could either continue to occupy the dwelling by paying the other fixed charges (taxes, insurance, etc.) or turn in its paid-up stock to the company at its surrender value.

Applications were considerably in excess of the number of dwellings. By the fall of 1922, it was reported, 90 houses were nearing completion and it was hoped that "many more" could be built in 1923. This hope, however, was not realized.

Fate of the Project

One of the aims, as already noted, was the collective ownership of homes. This was also a provision of the law under which the

[15] Daniel W. Hoan, 1928, quoted in The New Day for Housing, p. 163.

[16] Report of Proceedings of Third Congress of The Cooperative League, 1922, p. 105.

Garden Homes Co. was formed; title was to be held by the corporation, with leases issued to the tenant-owners. It was explained that it was not the purpose of cooperative associations, such as the Garden Homes Co., to "enable tenants to obtain homes at bottom prices by building collectively and then to allow the individuals to own and sell them for profit to others. Such a policy destroys the cooperative society."[16]

Whatever the plan of the sponsors, the collective-ownership idea could not be carried through. The tenant-owners, or at least some of them, became dissatisfied with the lease arrangement; they "felt that by becoming owners of the homes, with a deed, they would be able to sell at a profit."[17] This attitude was attributed to the fact that the secretary of the company "did not take pains to sell this [the cooperative] idea to all who took the homes."[17] Agitation was started to change the law to permit outright sale, and such an amendment was obtained in 1923, less than a year after the first tenant moved in.

This change, of course, altered the whole character of the enterprise. However, the chief sponsor of the project remained of the opinion that, in spite of the fact that the cooperative character of the project was thus jettisoned, the venture "was a remarkable success, from every point of view."[17]

BUILDING-GUILD EXPERIMENT, SUFFERN (N. Y.)

An assault on the high cost of home owning, through a system of building guilds, was carried on in several places in New York and New Jersey in the middle and late 1930's, using a plan worked out by Ralph Borsodi, economist, writer, and teacher. The experiment began in a small way about 1935. Its declared objects were (1) to furnish honest construction and at the same time lower the cost of building, (2) to eliminate contracting and workers' slow-down methods, (3) to stabilize work and provide year-round employment, (4) to "end commercial exploitation of the home builder," and (5) to provide greater security to capital while at the same time providing labor with a higher yearly income.

Each homestead project involved four parties—the Independence Foundation, a homestead association, the individual homesteader, and a "building guild." The Independence Foundation was a nonprofit agency formed to sponsor, finance, and provide technical supervision and cost accounting for the various building projects. Its funds were raised through the public sale of its investment certificates (bearing 6 percent interest) and loans from banks, building and loan associations, and other agencies. It purchased land at acreage rates and subdivided it into plots large enough to provide space for subsistence gardening.

---

[16] Report of Proceedings of Third Congress of The Cooperative League, 1922, p. 105.

[17] The New Day in Housing, p. 163.

In connection with each project, a homestead association was formed by the Foundation to purchase the land, over a period of years, from the Foundation and hold it as a collective agency of the individual homesteaders, granting use of the land to them under a 99-year lease. The houses in the homestead project, on the other hand, were held in fee simple by the occupying homesteaders, and were constructed by an association of building-trades workers (guild) formed for the purpose. Each homestead association had a board of five members, all residents of the community and elected annually for 5-year terms. However, the treasurer of the Independence Foundation was to serve also as treasurer of the homestead association until the latter's obligations to the Foundation had been fulfilled. In the affairs of the association each homeowner had a single vote.

Procedures Involved

An individual desiring to participate in a homestead project would apply to the homestead association for membership, accompanying his application by a $25 membership fee. This was, actually, often the only cash furnished by the prospective homeowner until after he became a resident of the project. If accepted for membership he signed an "indenture" covering the terms under which occupancy of the land was granted to him. Under this agreement he bound himself to pay a "land assessment" in an amount (calculated by the homestead association each year) sufficient to cover his share of taxes, interest on capital investment, maintenance of roads, utilities, etc., and 0.5 percent amortization on the land cost. The agreement likewise provided that for 20 years the property was to be used exclusively for "homesteading purposes." The latter was defined to mean "property used primarily for the residence of the family group and for farming and creative work in the home, studio, workshop, or on the land by the individuals composing such family group." Any use of the property for "mercantile, commercial manufacturing, or industrial purposes" required the special consent of the homestead association.

All of the member's transactions with regard to the land were thus carried on through the medium of the homestead association.

A separate arrangement covered the construction of and payment for his house. Having been admitted as a prospective homesteader, he could then apply for a loan from the Independence Foundation in an amount sufficient to cover cost of construction of the dwelling and necessary improvements on the plot of land he chose. This "loan" was really a credit, for the Foundation took care of the actual expenditure of it, making advances of funds to the guild and paying vouchers for work actually completed. In return, the homesteader obligated himself to make regular monthly payments on the principal, with interest at 6 percent calculated on the monthly unpaid balances. These payments were made directly to the Foundation and varied, of course, according to the size and style of his dwelling. However, the total costs could be, and were, reduced by savings made under the guild system and by the owner's contributing his own labor on various parts of the job.

In the case of a member's withdrawal from the association, his "relative property rights and interests" in the common property of the association were to be determined according to the "ratio of the equity in the association's capital investment created by the member to that of the aggregate created by all the members."[18] In case of dispute on this or other matters in his relation to the homestead association, the member had the right of appeal to a board of three arbitrators.

How the Guild System Operated

As it happened, conditions were ripe for the experiment. At the time the first group of building workers was brought together, in 1936, the general employment situation was bad and the building trades were in the mood to try anything that offered the prospect of work. Under the plan presented to them, although the current union scale could not be paid, 12 months' steady employment was guaranteed; this, in an industry known for its seasonal unemployment, was likely to result in greater annual earnings than under the usual hourly rate. The men found the idea acceptable and the first group was organized into a "guild" and put to work.

Each guild consisted of a "guildmaster" and a crew including several carpenters, painters, and odd-job men. A plumber and an electrician worked for several guilds jointly. Although the over-all planning was done by the Foundation's staff, the actual operations on a particular contract were the responsibility of the guildmaster. Each crew member had a single vote in the conduct of the affairs of the guild. In a legal sense, the guilds were partnerships of the members.

The construction of each dwelling was governed by a contract between the individual homesteader ("proprietor") and the guild, approved by the Foundation. It called for construction to be carried out on the basis of estimates by the guild, but actually all such estimates were made by the technical staff of the Foundation. A supplementary agreement between the guild and the Foundation stipulated that these estimates were to be at substantially the same level as "prevailing charges by responsible contractors for work of equal quality." They covered interest, depreciation, repairs, and other costs incidental to the use of machinery and equipment of the guild, plus 10 percent of basic costs to cover sales, accounting, and general office expenses, 2½ percent for contingency reserves, and 2½ percent to cover any service and repairs necessary during the first year after construction was finished. It was also stipulated that the purchaser should have the right to inspect the books and make such audits as were necessary to verify the accuracy of his account, for 1 year after the final account was tendered him. Any savings between the total estimated cost and the actual cost would be divided equally between the bonus fund of the guild and the homeowner; if a loss was entailed, it was to be born in equal parts by guild and owner.

---

[18] Bylaws of the Bayard Lane [homestead] Association, Suffern, N. Y.

Every contract between the guild and the Foundation included the provision that 10 percent of the total basic costs of each construction contract should be paid to the Foundation as long as it acted as financing agent. Whenever its actual costs fell below this figure the difference would be rebated to the guild.

A "drawing account" from which individual guild members were compensated was created by charging against each home owner's loan credit the time spent by each class of worker in the construction of the house, on the basis of a "unit" rate per hour. Thus, the unit rate for the Rockland Building Guild for the year 1939 was 5 cents. The various classes of workers were assigned weights or "ratios" which, multiplied by the unit, yielded their actual hourly remuneration, as shown in table 2.

TABLE 2.—*Rates of pay estimated for members of Rockland Building Guild, 1939*

Class of worker	Probational members		Active and associate members		
	Craft ratio	Hourly rate (ratio x 5)	Craft ratio	Hourly rate (ratio x 5)	Annual rate
		Cents		*Cents*	
Master journeyman	14	70	15	75	$1,716
Journeyman, first class	12	60	13	65	1,487
Journeyman, second class	10	50	11	55	1,258
Senior apprentice	9	45	10	50	1,144
Junior apprentice	8	40	9	45	1,030
Laborer	7	35	8	40	915

Work was on the basis of a 44-hour week. Active and associate members received pay for 6 holidays (New Year's Day, Memorial Day, July 4, Labor Day, Thanksgiving, and Christmas) for 8 hours unless the holiday fell on Saturday, in which case 4 hours were paid for.

The "drawing account" was established in order to provide living xpenses for the crew members while the job was in process. The rate f basic unit and hourly pay established, it was pointed out, were really immaterial in the long run, for the men's total earnings on a job were directly related to the actual savings made on the total estimated costs for that job. These, as already noted, were divided between the men's bonus fund and the home owner. From the bonus fund thus established the guildsmen received additional payments once a year. This arrangement gave a direct incentive to the men to reduce the actual construction costs as much as possible.

The records of the Ramapo Building Guild show that, for the second half of the year 1937, the 19 guildsmen received a bonus of $6.97, for the first half of 1938 a bonus of $37.81, and for the second half of 1938 one of $38.22. This progressive increase in the size of the bonus may well have been a reflection of the increasing realization by the men where their interests lay and of their consequent rise in efficiency and productiveness.

There were other possible increments to their income, also. Thus, if the actual outlays from the 2½ percent set aside for servicing and repairs fell below that amount, half of the sum remaining was to be divided among the crew at the end of 1 year after the job was finished; likewise, half of any savings on the 2½ percent for contingent expenses was to be so divided, at the end of the second year after the job was complete.[19]

Although in the beginning the guilds were financed entirely by the Foundation in order to get them going, own capital was gradually built up by means of a deduction of not less than 5 percent from each man's advances from the "drawing account," deposited to his credit on the guild books. This capital was used for the purchase of new equipment, repairs, etc. In the event of a guild member's permanent withdrawal, the sum of his credit was to be refunded to him. The private property of the members was not subject to seizure for debts of the guild.

Results of the Experiment

The Independence Foundation was in existence for 3 years. During that time it lent, for land and dwellings, some $200,000. Under its auspices eight guilds were established[20] and some 50 houses were built. The first project of 16 houses in Suffern, N. Y., was followed by others in West Nyack and Ossining, N. Y., Ringwood, N. J., and Feasterville, Pa. It ceased operations at the beginning of the war, when wartime restrictions on construction stopped all private building and when considerably higher earnings could be had by guild members, in war industries. On its demise all of the projects, except the

---

[19] The other half was rebated to the home owner concerned.

[20] These were the Ramapo Building Guild, Rockland Building Guild, Clarkstown Building Guild, Sloatsburg Building Guild, Twin Ridge Building Guild, Becraft Building Guild, Sterling Building Guild, and New Castle Building Guild.

Bryn Gwelyd [21] Homesteads (Pennsylvania), reverted to the fee-simple plan of ownership of the land (as noted, the ownership of the houses had always been on that basis).

In the opinion of the sponsors of the plan, the experiment demonstrated that, with a continuous development of new units under the supervision of a central agency, it was possible to insure practically continuous employment to guild members, with larger annual earnings than were usual under the intermittent operation customary in the building trades. However, under guild operation, the normal craft lines were blurred and for this reason, if no other, the leaders in the Foundation realized that it would probably be impossible to obtain the cooperation of the building-trades craft unions in normal times.

The experiment also indicated the possibilities of greater efficiency in construction and of consequent savings to both workers and home-owners. The originator of the guild plan is of the opinion that the essential requirement in a plan of this kind is that the estimating, planning, accounting, and technical work (legal matters, land acquisition, architectural service) be done by a competent staff of some outside, impartial body (in this case, the Independence Foundation) in which both workers and home owners have confidence. He emphasizes that considerable savings could also be made through cooperative buying of building materials, fittings, equipment, etc.—not yet available generally in the distributive cooperative movement.[22]

Because of the nonprofit feature of the plan (no "profits" were made at any stage) and because of the incentives inherent in the guild system, substantial savings were made even without such cooperative purchasing. Thus, a report of the Foundation in the August 19, 1939, issue of the Independence Foundation News, stated that on 38 contracts for individual houses, then completed, the aggregate estimated cost was $111,965 and the actual cost $104,134. Savings amounted to $7,319, which were divided between guild members and home owners.

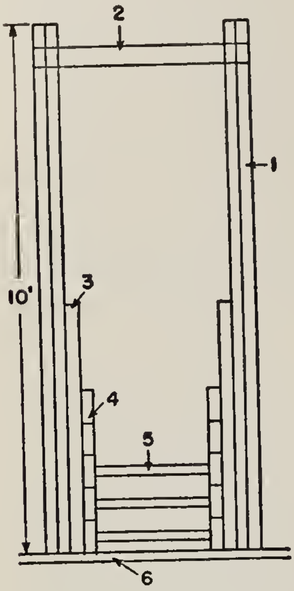
[21] Bryn Gwelyd is Welsh for "Hill of Vision."

[22] See pp. 85 and 86 for supplies and services available through cooperative wholesales.

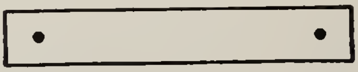
APPENDIX A.—Movable Forms Used in Laying Stone Walls at Penn-Craft

The following sketches, with explanatory material, show how simple forms were devised to aid unskilled workmen to lay stone walls for their houses at the Penn-Craft project.

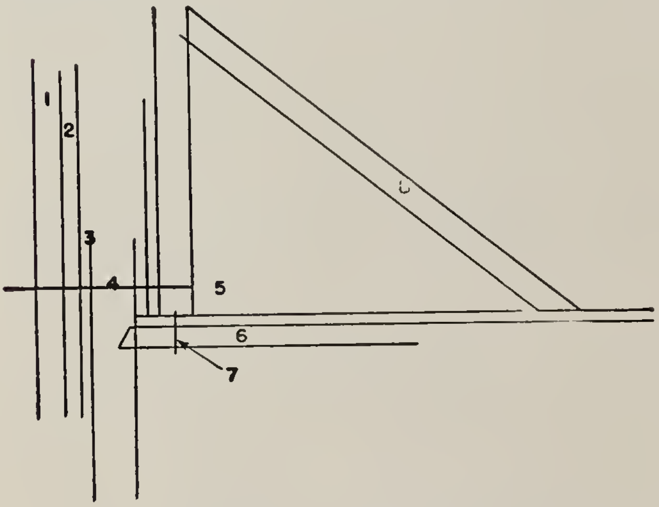


Cross section of forms and posts.

1. *Form post:* Made of 2—2 x 4—10 spiked or bolted together with ½″ iron pin fastened in bottom end, extending through bottom cross board #6.
2. *Top cross board*—Any one inch scrap piece nailed on the two posts to hold them at same width apart as at bottom.
3. *2 x 2 Release stick*—Approx. 36″ long. Is the key board for unlocking forms when ready to move the board upward for the next set.
4. *2 x 10 form plank:* These boards form the inside and outside walls of the form against which the stone is laid. These planks can be used later for floor joist or whatever they may be needed for. A few of them will have to be cut to fit short jogs in the walls.
5. *2 x 2 Release blocks:* These blocks are cut the exact width of the wall that one desires to build. Their job is to hold the form plank snugly against the 2 x 2 release sticks until stone is laid in the form, at which time the release blocks are removed or moved to a new place which needs temporary blocking.



6. *Bottom cross board:* This board is used in starting basement walls on the clay floor of the foundation. No footer is needed where a solid 16″ stone wall is to be built. The cross-board is drilled to receive the ½″ pins in the ends of the form posts as shown in the sketch below. This board is left in the wall. It need not be anything more than a scrap piece of 1″ board sufficiently long to serve the purpose. The length will depend upon the width of the wall to be built.



1. Form post.
2. Release stick.
3. Form plank.
4. Wire (#9) to bind outer post to inner post.
5. Subfloor.
6. Floor joist.
7. Iron pin in end of post-hole drilled in subfloor to hold it firm.
8. Brace to subfloor to keep wall plumb.

Sketch of first or second floor assembly

APPENDIX B.—Housing Supplies and Services Available Through Cooperative Wholesale Associations

The following table lists the cooperative wholesales that provide either building materials or service in the field of housing and shows for each the territory in which they operate and the commodities or services available through them.

Housing supplies and services provided by consumers' cooperative wholesales

Association	Trading territory	Commodities handled	Other housing services
National association			
National Cooperatives, 343 S. Dearborn St., Chicago 4, Ill.	United States, Canada	Galvanized and asphalt roofing, cedar shingles, nails.[1]	
Regional associations			
Associated Cooperatives of California, 815 Lydia St., Oakland 7, Calif.	California, Nevada	Lumber and other building supplies	Advice on organization, legal matters, and land acquisition.
Central States Cooperatives, 1336 Fullerton Ave., Chicago 14, Ill.	Illinois, Indiana, Ohio, southern Michigan.	Lumber, sash, roofing, building hardware and other building supplies.	
Indiana Farm Bureau Cooperative Association, 47 South Pennsylvania St., Indianapolis 9, Ind.	Indiana	Lumber, paint, shingles, steel, building tile and blocks, hardware, and other building supplies.	Homestead-improvement program.
Farm Bureau Services, 221 North Cedar St., Lansing, Mich.	Michigan	Nails and laminated rafters.	
Midland Cooperative Wholesale, 739 Johnson St. N. E., Minneapolis 13, Minn.	Southern Minnesota, southern Wisconsin.	Paint, wood and asphalt shingles, steel and aluminum sheets, paper roofing, nails, pipe, and some building hardware.	Assistance in organization.
Farmers Union Central Exchange, P. O. Box G, St. Paul, Minn.	Minnesota, Montana, North and South Dakota, northern Wyoming.	Paint, lumber, asphalt roofing and siding, nails and other hardware.	
Farmers Lumber & Supply Co.,[2] 1961 University Ave., St. Paul 4, Minn.	Iowa, Minnesota, Montana, Nebraska, North Dakota, South Dakota.	Lumber (75 yards in States named).	
Consumers Cooperative Association, 318 East 10th St., Kansas City 13, Mo.	Missouri, Nebraska, Kansas, southern North Dakota, South Dakota, southern Wyoming, Colorado, Iowa, Oklahoma.	Lumber,[3] composition roofing, Portland cement, brick, and tile, steel, red-cedar shingles, paint,[4] millwork, sash and doors, building hardware.	Legal department; architectural service (building plans and specifications, advice on building materials, etc.).
Farmers Union State Exchange, 39th and Leavenworth Sts., Omaha 5, Nebr.	Nebraska	Asphalt and steel roofing.	
Eastern Cooperative Wholesale, 44 West 143d St., New York 30, N. Y.	New England, Delaware, New Jersey, New York, Pennsylvania, Maryland, District of Columbia, northern Virginia.	Lumber, roofing, building hardware, tile, some interior fixtures.	Full-time adviser on organization, land acquisition, architectural planning, etc.
Grange Cooperative Wholesale, 3104 Western Ave., Seattle 1, Wash.	Washington	Roofing and nails.	
Central Cooperative Wholesale, Superior, Wis.	Northern Minnesota, northern Wisconsin.	Complete line of building materials and paint.	House plans, advice on building materials.
District associations			
Northland Cooperative Federation, Rock, Mich.	Upper Peninsula of Michigan		House insulation.
Range Cooperative Federation, Virginia, Minn.	Minnesota, Mesabi Range district	Lumber.	
Cooperative Services, Maple, Wis.	Northern Wisconsin	Lumber and complete line of building supplies.	

[1] Plans addition of many more items. [2] Subsidiary of Farmers Union Grain Terminal Association. [3] Own sawmill. [4] Own plant.

Appendix C.—Selected List of References on Housing

Burroughs, Roy J.

Farmers' cooperative construction service. (*In* Land Policy Review, U. S. Department of Agriculture, Bureau of Agricultural Economics (Washington), winter 1945, pp. 16–21.) Price 10 cents.*

Presents a plan for a Nation-wide farmers' cooperative construction service, including the construction of homes as well as farm buildings and the servicing of equipment. Proposes that the regional farmers' cooperative wholesales take the initiative in forming a national association.

Bauer, Catherine.

Housing in the United States: Problems and policy. 28 pp. (Reprinted from International Labor Review, July 1945.) Montreal, International Labor Office, 1945. Price 10 cents.

A critical analysis of the housing situation, of public housing, of FHA insurance, and of possibilities under present housing legislation.

—— Modern housing. Boston and New York, Houghton Mifflin Co., 1934. 331 pp., illus.

In addition to historical material, beginning with the 19th century, contains detailed data on elements of modern housing—standards, location, lay-out and building arrangement, building types and dwelling plans, construction, architecture, etc.

Chase, Stuart.

The case against home ownership. (*In* Survey Graphic, May 1938, pp. 261–267.)

Gray, George Herbert.

Housing and citizenship: A study of low-cost housing. New York, Reinhold Publishing Corporation, 1946. 254 pp., bibliography, charts, plans, illus.

An exhaustive report dealing with the historic and philosophic as well as the social, economic, and technological background of housing in both the United States and Europe. Shows how public housing policy has developed, illustrated with accounts of many projects and showing their advantages and shortcomings. There are chapters dealing with determining factors in cost of housing and rent, and with designs for low-cost dwellings. Accomplishments of various Federal housing agencies in the United States are reviewed and appraised. The author also presents a comprehensive program for postwar housing in this country, including therein an outline of policies that should be changed and a proposal for a national council of housing.

Halbert, Blanche, *editor.*

The better homes manual. Chicago, University of Chicago Press, 1931.

Detailed discussion of the various "requirements for good housing"—cost, site, architecture, materials, lighting, etc.

Kirkham, John Edward.

How to build your own home of earth. Oklahoma Engineering Experiment Station Publication No. 61. Stillwater, Oklahoma Agricultural and Mechanical College, 1946. 37 pp., diagrams, illus.

With the object of stimulating "personal initiative in people for building their own homes," at a cost that they can afford, the author (on the basis of his own experience with a house now 8 years old) describes the various processes, and gives diagrams for equipment for hand labor in building a house of earth.

U. S. Department of Labor. *Bureau of Labor Statistics.*

Organization and management of cooperative and mutual housing associations. (*Its* Bulletin No. 858.) Washington, 1946. 65 pp. Price 20 cents.*

Discusses general principles of cooperative housing, site and type of project, community and architectural planning, financing, membership relations, administration and management, tax status, etc. Appendixes give model bylaws, sample share subscription agreement, model lease, and citations of cooperative and housing laws.

U. S. National Housing Agency. *Office of the Administrator.*

Mutual housing: A Veterans' guide. Washington, 1947. 55 pp. Price 15 cents.*

Covers origination and organization, financing, construction, operation and management, etc.

—— *Federal Public Housing Authority.*

Manual of policy and procedure. Section 3555:2—Sales to mutual ownership corporations of Federally owned permanent war housing projects developed under the Lanham Act, Public Laws 781 and 9. Approved January 18, 1946. (Mimeographed.)

—— *Federal Housing Administration.*

A handbook on urban redevelopment for cities in the United States. Washington, 1941. 105 pp. (FHA Form No. 2389.) Price 15 cents.*

—— —— Principles of planning small houses. (*Its* Technical Bulletin No. 4., revised June 1, 1946.) Washington, 1945. 44 pp., diagrams, illus.

—— —— Housing Costs: Where the housing dollar goes. (*Its* Bulletin No. 2.) Washington 1944. 48 pp. Price 10 cents.*

Wood, Edith Elmer.

Recent trends in American housing. New York, The Macmillan Co., 1931. 317 pp.

An analysis of the housing situation in the early 1930's (much of which is applicable today). Chapter X deals with cooperative housing.

Wright, Henry.

Rehousing urban America. New York, Columbia University Press, 1935. 173 pp., charts, diagrams, illus.

A critical analysis of a number of group projects (single, row, and apartment dwellings) here and abroad. Contains chapters on new methods of construction, quality of living space, and analytical and cost studies. Addenda relate to desirable standards for various parts of the dwelling.

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., February 14, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on collective bargaining with associations and groups of employers. The study is based on an examination of the collective-bargaining agreements and other source materials on file with the Bureau of Labor Statistics. The report provides the most recent picture of the extent to which unions negotiate agreements with associations and groups of employers. It brings up to date the study prepared by the Bureau in 1939.

The report was prepared by the staff of the Industrial Relations Branch, Boris Stern, Chief.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 897 of the
United States Bureau of Labor Statistics

[From the Monthly Labor Review, March 1947]

Collective Bargaining With Associations and Groups of Employers[1]

Most of the examples of industry-wide bargaining in the United States are the product of generations of experience, and as a rule the employer-union relations in these industries have been remarkably stable and peaceful. In the pressed or blown glassware industry, one of the branches of glass and glassware having national bargaining, no major strike throughout the industry has occurred since collective bargaining began with an employers' association in 1888. Similar conditions have prevailed in the pottery industry since 1922. The 1946 contract between the National Automatic Sprinkler and Fire Control Association and the United Association of Journeymen Plumbers and Steamfitters (AFL) is a revision of the original agreement of 1915; and the 1946 agreement between the Anthracite Coal Operators and the United Mine Workers of America (AFL) is a compilation of resolutions, revisions, rulings, and decisions dating back to 1903. Bargaining on an industry basis exists in the elevator installation and repair, installation of automatic sprinklers, pottery and related products, stove making, and wall-paper industries, and in coal mining.

Agreements covering all the employers in an industry within a geographic region are somewhat more numerous than those having application throughout an entire industry. Even more numerous are the instances in which associations or groups of employers are dealt with on a city-wide or metropolitan area basis. In this study, the existing extent and the areas of bargaining with associations and groups of employers are described. The most significant extension of this form of bargaining in recent years occurred during World War II in the shipbuilding industry. The Metal Trades Department of the American Federation of Labor negotiated a master agreement during 1941 with Pacific Coast shipyards organized by unions affiliated with the AFL. Prior to this time, joint agreements had been signed by these unions on the West Coast with employers in a single day. In other industries, since 1939, the practice only widened in those that had used this method of dealing for many years. The number of workers covered by these agreements increased somewhat as more of the Nation's industry became organized and was brought under agreement. However, the relative proportion covered in most industries did not change greatly.

---

[1] Prepared by Roy M. Patterson and the staff of the Collective Bargaining Division of the Bureau's Industrial Relations Branch, under the general supervision of Harold S. Roberts, Chief. Special credit is also due for the contributions made by Abraham Weiss, Jesse Carpenter, and Philomena Marquardt.

Few of the examples of collective bargaining on an industry, geographic, or city basis occurred in the mass-production industries, although a single agreement in the automobile industry, for instance, may cover many more employees than an association agreement covering every employer in an industry or trade within the same city. In mass-production industries, trends are developing toward standardized conditions in large segments of industries through corporation-wide collective bargaining. The efforts of unions are directed first toward bringing all the plants of a given large corporation, regardless of geographic location, within the scope of a single agreement. An example is the corporation-wide bargaining between the Ford Motor Co. and the United Automobile, Aircraft and Agricultural Implement Workers of America (CIO). Notwithstanding the great number of workers affected, corporation-wide bargaining differs widely from multi-employer collective bargaining which is the subject of the present study.

Early in 1947, more than 4 million workers were covered by agreements negotiated between trade-unions and associations and groups of employers. These are about equally divided between manufacturing and nonmanufacturing industries. Approximately a fourth of all workers covered by union agreements in manufacturing and a third of such workers in nonmanufacturing are working under agreements negotiated with groups or associations of employers. The agreements were negotiated by one or more unions (1) with a formal or informal association of employers or (2) with informal multi-employer groups. In presenting the information on agreements, no attempt was made to distinguish between agreements with associations and with other multi-employer groups. Identical agreements signed by separate employers with the same union were included, if there appeared to have been negotiations with a group or committee of employers.

Worker Coverage of Group Bargaining

In table 1, the extent of association and employer-group bargaining is shown, based upon the percent of total workers under agreement in the respective industries.

TABLE 1.—*Percent of All Workers Under Agreement Who Are Covered by Agreements With Associations and Groups of Employers, by Industry*

80–100 percent	60–79 percent	40–59 percent	20–39 percent
Clothing, men's Clothing, women's Coal mining Laundry and cleaning and dyeing Longshoring Maritime Shipbuilding and boatbuilding [1]	Baking Book and job printing and publishing Canning and preserving foods Construction Dyeing and finishing textiles Glass and glassware Malt liquors Pottery and related products Trucking and warehousing.	Building service and maintenance Leather products, other Newspaper and periodical printing and publishing	Beverages, nonalcoholic Hosiery Hotels and restaurants Jewelry and silverware Lumber Shoes, cut stock and findings Trade

0–19 percent
Agricultural machinery and tractors Aircraft and parts Automobiles and parts Bus and streetcar, local Bus lines, intercity Carpets and rugs, wool Cement Chemicals, excluding rayon and allied products Clerical and professional, excluding transportation, communication, theaters, and newspapers Cotton textiles Confectionery products Crude petroleum and natural gas Dairy products Electrical machinery, equipment and appliances Flour and other grain products Furniture Knit goods, except hosiery Leather (tanned, curried and finished) Light and power Machinery and machine tools Meat packing Metal mining Motorcycles, bicycles, and parts Newspaper offices Nonferrous metals and products, except jewelry and silverware Nonmetallic mining and quarrying Paper and pulp Paper products Petroleum and coal products, except refining Petroleum refining Railroad equipment Rayon and allied products Rubber products Silk and rayon textiles Steel, basic Steel products Stone and clay products, other Sugar, beet and cane Telegraph service and maintenance Telephone service and maintenance Tobacco manufactures Woolen and worsted textiles

[1] During World War II most of the industry was covered by tripartite zone standard agreements, signed by representatives of unions, employers, and certain government agencies. The principal association agreement other than the zone standard agreements is between Pacific Coast Shipbuilders and the Metal Trades Department of the AFL, covering yards organized by AFL unions.

Area Coverage of Group Bargaining

The industries are classified by area of bargaining in table 2.

TABLE 2.—*Area of Bargaining With Associations or Groups of Employers, by Industry*

Bargaining on a national or industry-wide scale	Bargaining by geographic (regional) areas	Bargaining within a city, county, or metropolitan area
Coal mining Elevator installation and repair Glass and glassware Installation of automatic sprinklers Pottery and related products Stoves Wall paper	Canning and preserving foods [1] Dyeing and finishing textiles [1] Fishing Hosiery Leather (tanned, curried, and finished) [1] Longshoring [1] Lumber [1] Maritime Metal mining Nonferrous metals and products, except jewelry and silverware [1] Paper and pulp Shoes, cut stock and findings [1]	Baking Beverages, nonalcoholic Book and job printing and publishing Building service and maintenance Clothing, men's [2] Clothing, women's [2] Confectionery products Construction Cotton textiles Dairy products Furniture [2] Hotel and restaurant Jewelry and silverware Knit goods Laundry and cleaning and dyeing Leather products, other Malt liquors Meat packing Newspaper printing and publishing Paper products, except wall paper Silk and rayon textiles Steel products, except stoves [2] Tobacco Trade [2] Trucking and warehousing [2]

[1] There also is some bargaining on a city, county, and/or metropolitan area basis.

[2] There also is some bargaining on a regional and/or industry-wide basis.

Approach to Standardization of Working Conditions

One of the major efforts of labor unions in this country has been directed toward the standardization of working conditions throughout an industry or area, in order to lift substandard wages and to eliminate or reduce the factors of wages and hours in competitive costs. One of the ways the labor movement has sought to attain this objective has been by pressing for Federal or State legislation for the protection of certain groups of workers or to establish minimum standards applicable to all workers. Legislation has been sought especially for women and minors on the ground that the interests of society as a whole require that the health and welfare of these groups of workers be protected, and also because they often are in a weak bargaining position and might be used to lower the standards of all workers. Certain minimum standards of health, safety, and sanitation were established by legislation when large sections of the population felt a need for such, and the labor movement from time to time has favored legislative action as the most effective remedy for problems of health and safety. Under the Fair Labor Standards Act, minimum wage and hour standards have been established in much of American industry, thus raising the area of collective bargaining on these issues to higher levels.

Prior to World War II the approach to standardization of wages and working conditions through governmental action was secondary as far as American trade-unions are concerned. Organized labor in this country has directed its chief efforts toward standardization by means of collective bargaining. For this reason the labor movement generally has encouraged parallel organizations of employers for collective-bargaining purposes, in order to obtain extended coverage under one agreement. In some industries the employers also have favored the extension of uniform wages and working conditions by making the terms of a collective-bargaining agreement applicable to a large segment of an industry. When collective bargaining with groups or associations of employers has proved impracticable or impossible, some unions have utilized the technique of presenting identical agreements to the employers within an industry or competitive area. This latter method usually is practicable only in instances where there are a large number of small employers, particularly within a metropolitan area.

Although industry-wide trade associations have come to be a common characteristic of American business, the scope of employer groups or associations engaged in collective bargaining is generally much more limited. Within an industry, employers may be organized for purposes of collective bargaining on a city, regional or, in a few instances, nation-wide basis, or two or more such employer organizations may exist in the same area. As a rule, the unions work toward the extension of the collective-bargaining agreement to as wide a section of the industry as possible. In a number of cases the unions and employer organizations together have directed their efforts toward bringing unorganized sections of the industry within the scope of collective-bargaining agreements. A necessary corollary of dealing through employers' associations is a high degree of unionization among the employees.

During World War II, industry-wide production drives, settling of labor disputes by the National War Labor Board on the basis of industry or area practice, and the Government's wage stabilization policies all contributed to standardization of wages and working conditions throughout industries or areas. Directives of the National War Labor Board were influenced by precedent and prevailing practices in the industry or area and many agreements in the same industry came to have similar provisions on certain subjects. Frequently an order of the Board would affect several employers and the substance of the order would be incorporated into union agreements the employers might have negotiated, without regard to the existence of an employers' association. In the shipbuilding industry, in which a stabilization commission was established, tripartite "zone standard" agreements were negotiated, covering a limited number of subjects. The parties to the agreements were the Government itself and most of the employers and unions in the industry. The shipbuilding industry in the United States was divided into four zones, in each of which the "zone standards" determined practices with regard to those subjects covered by the agreements.

The attention directed to a few national associations with long records of collective bargaining should not be permitted to obscure thousands of employer organizations which have negotiated agreements on a regional or metropolitan basis and which affect hundreds of thousands of workers. These employer groups vary widely as to type, structure, procedure, and scope of activity. Some are temporary and highly informal, with no tangible evidences of permanent organization. Others have complex structures with elaborate constitutions and a staff of full-time employees. Between these extremes there are wide variations in organization, procedures, and functions.

Nation-Wide Collective Bargaining in the Coal Industry

In anthracite mining a single agreement is signed to cover the entire ndustry. In bituminous-coal mining, the union negotiated agreenents with the operators in the Central Competitive Field (Ohio, ndiana, Illinois, and West Virginia) from 1898 until 1927. The agreement for this area set the pattern for negotiations in other areas between districts of the union and local associations of coal-mine operators. The interstate bargaining relationship in the Central Competitive Field collapsed in 1927 and was not reestablished until after the passage of the National Industrial Recovery Act. In 1934 an agreement was signed with the operators in the Appalachian Area which served, as the previous interstate agreement had, as a pattern which the remainder of the industry generally followed. Districts of the United Mine Workers of America negotiate agreements with parallel associations of employers, which follow the terms of the Appalachian agreement. In 1941 the northern and southern groups of operators in the Appalachian area signed separate agreements with the union, and unified negotiations were not reestablished until 1945. In that year, the first industry-wide agreement in bituminous-coal mining was negotiated.

Following the break-down of negotiations between the union and the operators in the spring of 1946, which led to a Nation-wide soft-coal strike, and the rejection by both the union and the operators of President Truman's May 16 arbitration proposal, the President on May 21 "authorized and directed" the Secretary of the Interior to take over the mines. On May 29 an agreement was signed by John L. Lewis, president of the union, and J. A. Krug, Coal Mines Administrator and Secretary of the Interior. The agreement covered all the wines which were seized.

National Bargaining on the Railroads

The traditional bargaining unit in railroad transportation is the individual railroad system. The workers are organized on the basis of craft, and agreements with the various systems are negotiated by each craft union or by "system federations" of shop craft unions. Although the regular working agreements continue to be signed by systems, on occasion certain specific questions of major importance, as wages, have been settled on a Nation-wide basis. Negotiations are generally conducted by the nonoperating unions (clerical, maintenance, and shop crafts) and by the operating unions (train and engine service) separately with representatives of the railroads selected on a regional basis.

Other Industry or Trade-Wide Bargaining

The American examples of trade-wide bargaining of longest status occur in the pottery and glassware industries. Since the early years of this century, an annual meeting has been held between the representatives of the United States Potters' Association and the National Brotherhood of Operative Potters. The current agreement between these parties, for example, continues a provision for joint discharge committees first set up in 1913. Since 1888 the National Association of Manufacturers of Pressed and Blown Glassware, or its predecessor, has been meeting with the American Flint Glass Workers Union. The "Star Island Agreement" of 1903 established a grievance procedure which still is utilized in this industry. The Glass Bottle Blowers' Association of the United States and Canada signed its first national agreement in 1890 and currently has an agreement with the Glass Container Manufacturers' Institute which affects several thousand employees in the industry.

In each of these cases the bargaining agreements are confined chiefly to detailed piece-rate schedules, although a considerable body of "unwritten law" has developed to supplement the national agreement in governing employer-employee relations within a plant. Originally, the trade-wide bargaining was established to regulate the working conditions of highly skilled craftsmen within these industries. With the development of technological changes, one skilled occupation after another has been eliminated. As a result, the unions have extended their jurisdiction to include a major part of the workers in and around the plants and these skilled and semiskilled employees are now covered in the national agreements to the degree that they are unionized. In the glassware industry, however, there are some companies which have negotiated separate agreements. In the pottery industry virtually all of the vitreous and semivitreous branches of the industry are covered by the association agreement.

A different kind of bargaining relationship has been built up in the manufacture of flat glass. By far the major part of the production in this industry is centralized in two large producing companies. These companies, the Pittsburgh Plate Glass Co. and the Libby-Owens-Ford Glass Co., negotiate their agreements jointly, both with the Window Glass Cutters League (AFL) and the Federation of Glass, Ceramic and Silica Sand Workers (CIO), but each company signs separate, identical agreements. The two companies also collaborate in the administration of the agreement to insure uniform patterns of interpretation. Most of the other manufacturers are organized into the Fourcault Manufacturers' Association which negotiates the agreement with the unions.

There are a few other instances of industry-wide dealing, each of hem originating from the efforts of a highly skilled craft to protect ts conditions of employment. Among these are the Wall Paper Institute and the United Wall Paper Craftsmen and Workers of North America, covering wall paper printing; the National Automatic Sprinkler Association and the United Association of Journeymen Plumbers and Steamfitters of the United States and Canada, cover-ng sprinkler fitting; and the Manufacturers Protective and Development Association and the International Molders and Foundry Workers Union of North America, covering stove-molding and hot-water castings.

Employers engaged in the manufacture of paper-mill wire cloth sign similar agreements with the American Wire Weavers' Protective Association. Another instance of trade-wide bargaining occurs in the installation, repair, and maintenance of elevators. Although wage rates are negotiated locally, other working conditions are regulated by conferences between the National Elevator Manufacturing Industry, Inc., and the International Union of Elevator Constructors. A standard agreement is used in all localities, with the locally negotiated rates inserted as agreed upon.

The manufacture of wooden kegs and barrels should also be mentioned as an instance of national conferences between the employers and the union. The conferences, however, have resulted in no agreement on an industry scale and discussion of working conditions has been of far less importance than mutual discussion of trade-promotion plans.

Industry-Wide Bargaining in Mass-Production Industries

In the more recently organized, mass-production industries there are at present no examples of industry-wide collective bargaining resulting in a single union agreement covering the full range of employer-union relations. In a few such industries, however, certain bargaining relationships have come into existence which produce considerable uniformity in the agreements throughout an industry. In the rubber industry, for example, a wage-increase agreement was signed on March 2, 1946, by the four largest manufacturers, which affected a large proportion of the workers in the industry. This so-called "Big Four" agreement is limited in scope to a few subjects; it differs from the usual union agreement also in that it does not have the customary provisions relating to termination and renewal. The agreement provides: "This agreement shall finally dispose of all issues covered in these negotiations including all of the union's 7-point program for a period of 1 year except that during this 1-year period the general wage scale shall be subject to negotiation if conditions economically and in the industry warrant, but only on a four-company (Big Four) basis." If this joint relationship of the four corporations with the United Rubber, Cork, Linoleum and Plastic Workers of America is continued in the future, it may be possible to describe the collective bargaining in this industry as approaching industry-wide negotiations.

A degree of standardization has been achieved in the meat-packing industry through the medium of uniform expiration dates of the agreements with the principal packers. Certain agreements affecting a large number of workers negotiated by the United Packinghouse Workers of America (CIO) and by the Amalgamated Meat Cutters and Butcher Workmen of North America (AFL), covering various plants of the four largest corporations in the industry, have expired on the same day each year for several years.

Negotiation of Similar Agreements in the Steel Industry

In the basic steel industry in the United States there is no employers' association which engages in collective bargaining, yet a great deal of standardization in industrial relations has occurred in recent years. The industry is composed of two dominant groups of employers, one known as "Big Steel" and the other as "Little Steel." The first includes the United States Steel Corp. and its subsidiaries, and the second is made up of a number of independent companies. The Steel Workers Organizing Committee, now the United Steelworkers of America, first signed written agreements with the U. S. Steel Corp. in 1937 and since then, with a few exceptions, practically all of the basic steel industry has been brought under agreement. Even though there is no bargaining by employers' associations, the major provisions of agreements throughout the basic steel industry are similar. This degree of uniformity is occasioned by a number of factors, first among them probably being the predominant position of the United States Steel Corp. Agreements with this corporation tend to set the pattern for the rest of the industry. Also, by long-established practice the same wage adjustments generally are made throughout the industry at the same time. During World War II directives of the National War Labor Board, which generally were applicable to large sections of the industry, further encouraged the growth of uniform collective-bargaining practices. The United Steelworkers of America, the most important union in the industry, also tended to bring a degree of uniformity into the bargaining relationships and practices. Agreements with most of the employers in the basic steel industry will expire in February 1947, and negotiations are in process for new agreements. (Since this was written the parties have agreed to extend the agreements until April 30, 1947.)

Collective Bargaining by Geographic Areas

In the hosiery industry a bargaining relationship has existed between the Full-Fashioned Hosiery Manufacturers of America, Inc., and the American Federation of Hosiery Workers since 1927. The employers' association, originally covering only Philadelphia mills, now covers a major part of the northern section of the full-fashioned hosiery industry. Conferences occur annually, with occasional additional meetings on specific subjects. Under the agreement the joint relations are administered by a permanent impartial chairman.

In the textile industry there are association agreements between the Textile Workers' Union of America and associations of silk and rayon mills in a number of States. A joint arrangement of longer standing exists in the dyeing and finishing of textiles in nonintegrated mills. In cotton textiles in Massachusetts and in knit goods in Philadelphia and New York, many of the employers are members of associations which negotiate union agreements.

Maritime workers usually deal with employer organizations which represent the shipping operators on a given coast. Practically all the union agreements in the maritime industry are negotiated with associations or informal committees representing the employers. On the Pacific Coast the companies are organized into the Pacific American Shipowners Association. On the Atlantic and Gulf Coasts the most recent agreements were negotiated and signed by a Committee for Companies and Agents, Atlantic and Gulf Coasts, most of the members of which are also members of the American Merchant Marine Institute.

The Waterfront Employers of the Pacific Coast embraces employers of longshoremen along the entire West Coast; much of the work of the association, however, is carried on through affiliated local Waterfront Employers Associations in Seattle, Portland, San Francisco, and San Pedro (Los Angeles). The International Longshoremen's and Warehousemen's Union (CIO) negotiates a general cargo agreement with the coast-wide association, which signs "on behalf of" the four local organizations. Separate agreements covering dock workers and ship clerks are negotiated with each of the port associations. On the Atlantic Coast the International Longshoremen's Association (AFL) as a rule, negotiates separate agreements with employer associations in each port.[2]

In the Pacific Northwest the pulp and paper industry, although dealing elsewhere on the basis of individual companies, is combined into the Pacific Coast Association of Pulp and Paper Manufacturers which deals with the two national unions in the field. The unions, representing different occupations in the industry, are the International Brotherhood of Papermakers and the International Brotherhood of Pulp, Sulphite, and Paper Mill Workers. The employers' organization is described in the agreement as follows: "This Pacific Coast Association of Pulp and Paper Manufacturers * * * of which the signatory company is a member, is an employer association of a majority of the pulp and paper manufacturing companies in the Pacific Coast area, comprising the States of Washington, Oregon, and California, and as bargaining agent with authority to bind its members by a majority vote of such mills, has met with a bargaining committee from the signatory union for a period of years, beginning in 1934 * * *." Notwithstanding this provision, each company signs a separate document with the local unions which represent its employees.

---

[2] For some time there has been no formal federated organization of the unions in the maritime industry. For a few months during 1946, however, the CIO unions and an independent formed the committee for maritime unity for the purpose of joint negotiations with all employers simultaneously. The American Federation of Labor, also in 1946, established a Maritime Trades Department, composed of AFL unions in the industry. Most of the unlicensed personnel on the Atlantic Coast are represented by the National Maritime Union (CIO). On the West Coast these workers are represented principally by three unions, the Sailors' Union of the Pacific (AFL), the Pacific Coast Marine Firemen, Oilers, Watertenders and Wipers Association (independent), and the National Union of Marine Cooks and Stewards (CIO).

The lumber industry is one which is not yet well organized throughout the country but in which the dominant method of present dealing is through associations within the producing area. The Columbia Basin Loggers' Association and the Timber Producers' Association in Minnesota are examples of associations dealing with the union in this industry.

The fishing industry, particularly on the Pacific Coast where it is well organized, is an example of collective bargaining almost exclusively on an association basis. The employers, however, are organized into a number of separate associations, such as the Alaska Packers' Association and the Central Pacific Wholesale Fish Dealers' Association.

In retail trade, the National Association of Retail Meat Dealers, composed of affiliated State and local associations throughout the United States, negotiates with the Amalgamated Meat Cutters and Butcher Workmen of America. The national agreement between these parties, first negotiated in 1937, is confined to a statement of principles and policies of mutual interest to both parties, who agree to "give their aid and good offices to the execution of fair and reasonable contracts between local unions and affiliated associations in the various localities where the said unions and affiliated associations exist." The agreement further states that it is recognized "that local conditions require local treatment and that it is not practical or feasible to include in this agreement the matters of wages, hours, and conditions of employment." In the Midwest, the Central States Drivers' Council, an organ of the International Brotherhood of Teamsters, Chauffeurs, Warehousemen and Helpers of America (AFL) negotiates agreements with the Central States Area Employers Association Negotiating Committee. Collective bargaining in canning and preserving foods on the West Coast is largely on an association basis.

Most of the shipbuilding and boatbuilding industry on the West Coast is covered by a master agreement negotiated by the Metal Trades Department of the American Federation of Labor. During the war, as previously noted, bargaining on major issues in this industry was on a tripartite basis, and wages and certain other questions were determined by the zone standards. Issues not covered by the zone standards were settled in the ordinary processes of collective bargaining. At the present time the zone standards are still in effect.

Bargaining in the Needle Trades Within Metropolitan Areas

Outstanding examples of stable bargaining relationships over a long period of time between employers' associations and unions are found in the needle trades. In the men's and women's clothing, men's hats and millinery, and fur industries the earliest efforts of unions to organize were accompanied by efforts to combine into associations the employers within the producing area. Bargaining has become established in these industries, with highly developed industrial relations machinery within each of the metropolitan areas which are important as producing centers. These unions and employers' associations customarily make use of a permanent impartial chairman to administer the agreement and there are numerous examples of joint trade boards, stabilization commissions, and other similar bodies which deal on a day-to-day basis with the problems of the industry.

These industries all have the problem of "run-away" shops, which leave the unionized areas and, with the small capital investment required, are able to establish themselves in low-wage, semirural sections. This has been a major reason for the unions' insistence upon dealing on an association basis, for it is through the combined pressure of both the union and the employer association that these "run-away" shops can be brought under control. Another problem within these industries is the regulation of the jobber-contractor relationship. Jobbers have taken advantage of both the extreme seasonal fluctuations and the small investment required in setting up a shop to encourage an oversupply of contractors. Cut-throat competition among the contractors has been furthered by the frequent practice of establishing "fly by night" shops for the duration of a contract secured by underbidding regularly operating shops. Both the owners of shops operating under union conditions and their workers have thus faced a constant threat to industrial stability. Through collective bargaining, the oversupply of contractors has been dealt with and the jobber's responsibility for maintaining union conditions in his contract shops has been established. A large portion of the employer-union negotiations in the needle trades deal with these three-way problems, in addition to the usual wages, hours, and working conditions.

The employers within a given city are usually organized into more than one association within each of the needle trades. The basis of distinction is both the type of product and the classification of employers (i. e., jobbers, contractors, or inside manufacturers). The unions have frequently expressed a desire for more uniformity among the employers' organizations throughout the industry. Although a major part of the production in the country is covered by the New York City agreements alone, the unions have made repeated efforts over several decades to secure industry-wide dealing in the interests of national standardization. Thus far, however, only in men's clothing has there been a successful approach to industry-wide bargaining. For a number of years the Amalgamated Clothing Workers of America has negotiated major wage questions with the Clothing Manufacturers' Association of the United States and with the Shirt Industry.

Other City-Wide Bargaining

In many industries and trades characterized by numerous small establishments within a city, collective bargaining has been conducted with associations of employers within the city. In many cases the associations are formal organizations in which the association officers have the power to bind all members to the agreed terms of employment. In other cases the employers may unite informally and perhaps only for the duration of the bargaining conferences. In many instances the lack of a continuing employers' association makes no difference in the actual negotiation of the agreement, but complicates considerably the enforcement of the agreement.

In cases of city-wide bargaining the extent of coverage of the employers' association generally depends upon the strength of the union. It is common to find within a city an organized group of employers dealing with the union, while other employers within the same industry are organized into a separate association or have no organization. In some cases the union employers form an organized group within a trade association which also includes nonunion employers in the city.

There are probably 5,000 local or city employer associations throughout the country which deal with various unions. More of these are found in building construction than in any other single industry. Other examples, in which the predominant method of dealing is with city-wide associations, are brewing, retail trade, baking, printing and publishing, restaurants, trucking, and barber shops. An important development is found in the electrical machinery industry, where the United Electrical, Radio and Machine Workers of America (CIO) recently negotiated an agreement with the Electronics Manufacturers' Association, representing 20 employers in the New York City area. This association was formed at the insistence of the employers, who are relatively small and who previously had signed separate agreements. The employers desire, through negotiating a single blanket agreement, to achieve a degree of uniformity in wage and working conditions in order to reduce these as competitive factors in costs.

Associations of Employers Across Industry Lines

Employer-group federations embracing all types of business within a city are largely a development of the last 10 years and are concentrated in the Far Western States. Leader in this field is the San Francisco Employers Council, formed in 1939, and which in April 1945 had 1,995 members, 919 of whom were affiliated through their various industry groups. The other members were individuals or independent companies. The objectives of the council, as stated in its articles of incorporation, are (1) to encourage the organization of autonomous employer groups and cooperation among these groups in matters relating to labor relations; (2) "to promote the recognition and exercise of the right of employers to bargain collectively"; and (3) upon request, "to assist its members and others in matters relating to the negotiation, execution and performance of fair labor contracts." The council negotiates or participates in negotiations of agreements between its members and the unions in the city, and performs various other services.

Of a similar character is the Industrial Conference Board of, Tacoma, Wash.—an over-all agency for a number of independent companies and 15 or 20 employers' associations each of which has one or more union agreements. Both the Reno Employers Council of Reno, Nev., and the Silver Bow Employers Association of Butte, Mont., participate in the negotiation of labor contracts for their various employer groups. In Sacramento, Calif., the Sacramento Valley Associated Industries is the unifying agency for a dozen or more associations covering such varied fields as bowling alleys, beverages, furniture warehouses, taxicabs, machine shops, liquor and tobacco dealers, retail foods, wholesale bakeries, draymen, druggists, tire dealers, and building owners. Each association has a union contract signed in its behalf by an individual, who serves both as executive secretary to the associations and as general manager of the Associated Industries.

LABOR IN THE SOUTH

Introduction

The subject matter of this bulletin should contribute appreciably to our knowledge of southern labor conditions.[1] It does not, however, constitute an exhaustive analysis of the position of labor in the region. This is true even within the specific fields of inquiry. For example, it is quite impossible fully to explore trade-union development or wage differentials within the confines of single articles.

The definition of "South," as employed in this bulletin, is not entirely uniform. Except where a different coverage is specifically indicated, however, the term relates to 13 States. Nine of these States—Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, and Mississippi—are generally taken to comprise the Southeast; the remaining four—Arkansas, Louisiana, Oklahoma, and Texas—are in the Southwest. This tremendous region contains 843,812 square miles of territory; its population in July 1945 was estimated at 37,624,000, excluding armed forces overseas but including armed forces distributed by State of station. Civilian population was estimated at 35,416,000.

The South as thus defined is not a homogeneous area. There is great and rich diversity in the geography, economy, and culture of the region. It is necessary to emphasize this point because the analysis that follows deals largely, although by no means wholly, in aggregates and averages. This type of social arithmetic is an indispensable tool for many analytical and policy-making purposes, but by its very nature it conceals wide variations in social existence and experience.

If there is diversity in the South, there is also a measure of unity. This unity is partly historical and partly a reflection of the fact that from the colonial period to the present the South has remained predominantly agrarian. To agriculture must be added the economic activities that depend directly upon the forest resources of the region and upon the wealth, including petroleum, under the earth. The South has been primarily an exporter of raw and semifinished products; its industrial development began relatively late and under severe initial handicaps. The ante bellum South, for various reasons, did not encourage the growth of industrial enterprise; and even as late as 1930 a group of southern intellectuals could argue (in I'll Take My Stand) that the social cost of industrialism outweighed its benefits.

---

[1] This report is based on seven articles that appeared in the October 1946 issue of the Monthly Labor Review; a substantial amount of material has been added, most of which covers entirely new subjects.

Industrialization, however, has increased significantly. In 1880, less than 8 percent of the wage earners employed in manufacturing in the United States were in the 13 Southern States. By 1939 this percentage had risen to 17.2. Moreover, while the absolute level of factory employment declined sharply in the country as a whole between 1929 and 1939, there was a small increase in the level of manufacturing employment in the southern region. An average of 1,362,027 wage earners were employed in manufacturing in the South in 1939. Manufacturing employment in the South increased sharply during the war years.

The manufacturing base in the South has been comparatively narrow, resting largely upon the textile industries (principally cotton textiles and hosiery), lumber, furniture, and tobacco, with petroleum refining in the Southwest. Other industries (iron and steel, machinery, apparel, and a host of others) have been rather thinly represented. However, the war apparently has strengthened a tendency for the industrial structure of the South to broaden, partly as a result of the rise of essentially new industries and partly from decentralizing tendencies elsewhere. Texas is a conspicuous example, and the Southeast is vibrant with new industrial undertakings.

This bulletin deals with some of the basic factors affecting labor in the South. The analysis of key population and labor force characteristics is essential to any broad understanding of the position of labor in the region. The sections on income trends and levels and on wages and wage differentials provide, in conjunction with the section on living costs, insight into the relative economic position of the southern industrial worker and of other segments of the southern population. They also provide a basic explanation for the great migratory movements discussed in the section on labor supply. Changes in manufacturing employment during the war and immediate postwar periods are also analyzed.

Two sections relate to efforts by workers to improve their economic well-being through organization. The first of these traces the development of the trade-union movement in the South; the second deals with the comparatively small consumers' cooperative movement. Finally, sections are devoted to legislation enacted by the Southern States for the protection of labor or relating to labor organizations and collective bargaining, to the impact of the Fair Labor Standards Act on the South, to old-age and survivors' insurance and unemployment compensation, and to the rise of industry in the region.

I.—The Rise of Industry in the South [1]

Industrial enterprise has always been present in the South. During the colonial period a variety of relatively simple processing operations were performed on the products of southern fields and forests; various household industries supplied basic consumer needs; and by the time of the Revolution more complex forms of enterprise were beginning to emerge.

The colonial South had its grist mills for grinding corn and other grains and larger merchant mills to prepare flour for export and for sale in stores. Tobacco, the chief southern staple during the colonial period, had to be dried, sorted, and packed, and rice had to be cleaned and polished. A more complicated operation was the processing of indigo into marketable cakes. Sawmills became common throughout the South in the eighteenth century, and lumber, in addition to its local use, became a leading export item. The cooperage industry flourished. Potash and pearlash, obtained from the ashes of hardwoods and used for bleaching and in making soap and glass, were in great demand in both England and the Colonies. By 1700, naval stores—tar, pitch, rosin, and turpentine—had become the chief export of the Carolinas.

The household manufacture of such articles as shoes, clothing, kitchen utensils, farm tools, and furniture was widespread. Colonial textile manufactures were based primarily upon wool and to a more limited extent upon flax and hemp. Nearly every colonial home had its spinning wheel and hand loom. Fulling—a process of shrinking woolen fibers to produce a better fabric—gradually came to be done in local shops, the home weavers taking their cloth to the fulling mill just as they took their grain to the grist mill. Some planters employed their poorer neighbors to spin and weave; on the larger plantations slaves performed these tasks. In this way small surpluses of homespun were sometimes produced for local markets.

Iron works had been established in every colony except Georgia prior to the Revolution. Near the end of the colonial period, brickmaking made its appearance. The first settlers of Georgia made some pottery, and other potteries were established in the Carolinas. Clearly industry was not extensive in the South during the colonial period, but its development probably coincided as well with the needs of the southern economy as the exigencies of British colonial policy would permit.

---

Industry and the Rise of Cotton Culture

In 1810 manufactures in the South comprised over 20 percent of the value of all manufactures in the United States—a proportion since unequaled. It has been pointed out that "in 1810 the value of textiles produced was greater in North Carolina than in Massachusetts, and the census for that year records more homespun cotton manufactured in Virginia, South Carolina, and Georgia than in the other 13 States and Territories combined. Also more flax was spun in Virginia than in any other State."[2] As early as 1788 power spinning was carried on in South Carolina. To the considerable manufacture of textiles and iron in the South recorded in the census of 1810, such miscellaneous products as saltpeter, leather, rope, gunpowder, hemp, salt, distilled spirits, and maple sugar contributed a crude but important diversity.

This early industrial development ran up against a combination of factors in the southern economy that were to delay industrial growth for at least half a century. The invention of the cotton gin; an almost insatiable market for cotton fiber; the existence of vast areas of land suitable for cotton; and the institution of slavery—all of these factors conspired to foster cotton culture at the expense of other forms of enterprise. In 1826 southern cotton production exceeded 1 million bales; by 1850 production stood at over 2 million bales; and in 1860 about 5 million bales were raised.

Staple plantation agriculture tended to absorb the capital and managerial skill of the region. Capital was scarce, and such surpluses as arose went largely into the purchase of land or slaves; outside capital was, in general, neither sought nor attracted. White immigrants, who made up an appreciable proportion of the Nation's supply of skilled labor, generally avoided districts heavily populated by Negro slaves; in 1860 only 5 percent of the free population in the South was foreign-born, while immigrants made up 18 percent of the population of the rest of the country. Such factories as were established in the South typically depended upon the initiative and resources of one or a few individuals.

While cotton production was increasing fifteenfold between 1810 and 1860, southern industry failed to hold its own. However, there was progress in technology; new kinds of products were turned out, and household manufacture was steadily displaced by the growth of mills. Transportation barriers were lessened by the appearance of the river steamboat and by the introduction of railroads, in whose development the South pioneered. The abundant water power of the Piedmont was increasingly utilized, and coal production increased. But the relative decline in southern manufacturing was striking.

---

[2] Mary Anderson, Women's Place in Industry in Ten Southern States, Washington, Government Printing Office, 1931, (p. 2).

By 1860 the proportion of the value of the Nation's manufactures produced in the South was only half of its share in 1810, and no more than 10 percent of the Nation's wage earners were located in the region.

The manufactures started in the South during the 40 years before the Civil War were, by and large, a product of temporary depression in the cotton market. Even such depressions, however, did not effect a substantial realignment of resources, for the plantation system was insensitive to changes in economic demand, and small farmers reacted to lower cotton prices—if at all—by trying to increase production.

There was some development in textile manufacturing during the ante bellum period. The largest cotton mill in the South prior to the Civil War was established in 1847 by William Gregg at Graniteville, S. C. This mill contained 9,000 spindles and 300 looms, and employed 300 workers. The 1860 U. S. Census of Manufactures listed 603 textile mills of all types in the South, with an average employment of 25 workers. Of these establishments, 163 mills employing 10,187 workers were designated as cotton mills.

Next to textiles, iron manufacture was the leading southern industry during this period, differing from its colonial character in its substitution of magnetite for bog ore, in its occasional use of coal for smelting, and in the greater variety and refinement of its products. Between 1810 and 1860 the number of sawmills in Virginia increased from 112 to 779, and by 1855 Wilmington, N. C., and Mobile, Ala., were each exporting annually about 18,000,000 feet of lumber. Turpentine came to dominate naval stores production as distillation was simplified by introduction of the copper still, and a derivative—camphene—became popular as an illuminant. By 1860 Virginia was the leading flour manufacturing State in the South, possessing 1,383 flour mills and even an export market in Brazil. Tobacco manufacturing was stimulated about 1850 by discovery of the yellow tobacco leaf in North Carolina; its manufacture had started at Durham by 1858, but Louisville, Ky., and the James River area in Virginia remained the chief centers and pipe tobacco the chief product. Leather factories devoted largely to the manufacture of boots and shoes were common in the cattle-raising States; and in the grain areas there were small distilleries.

The Beginnings of Modern Industry

The Civil War and its aftermath profoundly dislocated the economic structure of the South. By 1880; however, a number of factors favorable to industrialization began to converge, and that year is generally taken to mark the beginning of the South's modern industrial era. One factor of very great importance was the change in public attitude toward industrial development. "Bring the mills to the cotton" became, in a sense, the slogan of a crusade. Falling cotton prices between 1866 and 1880 lent impetus to the movement. Capital for the early mills frequently was secured by community subscription from many small investors, supplemented by subscriptions from machinery manufacturers and advances from commission houses. Technical change was of tremendous importance in cotton manufacture. The ring spindle and the automatic loom greatly reduced the need for skilled labor, and the development of the humidifier and temperature regulator aided efficient cotton processing.

Between 1880 and 1900 the number of wage earners and the value of manufactures in the South increased about threefold (table 1). This represented a greater rate of industrialization than occurred throughout the country as a whole: the proportion of the Nation's wage earners in the South increased from 8 percent to 13 percent over the period, while the region's proportion of the value of manufactures rose from 6 percent to 8 percent (table 2).

The manufacture of cotton goods led the industrial advance. Significant support, however, came from the appearance or revitaliza-

tion of other industries founded upon new markets and technologies. It was during this period that the tobacco industry gave promise of its fabulous future, under the influence of the cigarette machine and North Carolina's popular yellow leaf. The important iron and steel industry concentrated around Birmingham, Ala., had its beginning in 1876 as the development of the open-hearth process permitted the utilization of local ore and coal. Lumbering took on added stature as the decline of northern timber sources stimulated cutting of southern yellow pine. In 1888 the manufacture of furniture began at High Point, N. C., now the second largest furniture center of the country. Local production of fertilizer, utilizing readily available raw materials, became increasingly important in order to maintain the fertility of soils steadily drained by the cultivation of cotton and tobacco. In cottonseed oil and cake, the cotton plant was found to have valuable subsidiary uses. And at the turn of the century discovery of the rich Spindletop field in Texas first brought the Southwest's phenomenal petroleum resources into view.

From the base established during the last two decades of the nineteenth century, southern industry expanded steadily. Between 1899 and 1919 the number of wage earners in manufacturing almost doubled, and the increase continued during the prosperous twenties and even (in face of a national decline in industrial employment) during the depressed thirties. By 1939 the value of southern manufactures exceeded $8,000,000,000 (table 1). Continued industrialization during World War II raised southern manufacturing output to new heights.

This industrial advance has been based upon a number of factors. The southern labor supply has been large relative to industrial employment opportunities. Because of the character of the labor market, industry in the South has been able, on the whole, to obtain labor at wage rates lower than those paid for comparable work in other parts of the country. A second factor has been the existence in the South of raw materials of various types to the fabrication of which the abundant labor supply has been adapted. Indeed, the industrialization of the South has involved chiefly the processing of southern raw materials for sale primarily outside the region—cotton textiles, pulp and paper products, tobacco, furniture, sugar, and petroleum products. Future development may include a greater variety of industries producing goods predominantly for local consumption and a larger representation of industries engaged in complex fabrication or assembly (e. g., machinery).

Industry itself is a great progenitor of industry. In the cotton mills, tobacco factories, blast furnaces, sawmills, furniture establishments, fertilizer plants, and oil refineries established in the South at the turn of the century there existed the germs of the subsequent rapid development. Tobacco profits were not only reinvested in the industry, but also found their way into the textile expansion and into the hydroelectric power development of the Piedmont. Railroads steadily displaced river traffic, and coal mining grew apace with the demand for steam power. In towns having both textile mills and furniture factories, the employment of women in the former and men in the latter boosted family income and at the same time helped to stabilize the local economy. The chemical revolution precipitated by World War I brought forth a myriad of new products from the South's store of cellulose (cotton and wood), hydrocarbons (petroleum, coal, and naval stores), and industrial elements (sulphur and fertilizer ingredients, particularly). The interaction of these and other developments produced markets, skills, profits, and attitudes propitious for the greater industrialization that was to come with World War II.

Growth of Leading Industries Before 1940

TEXTILE MANUFACTURES

Cotton-goods manufactures in the South doubled and redoubled in importance in the early decades of this century. Between 1899 and 1939 the Southeast's share of the spindles in the industry increased from 22 percent to 73 percent of the Nation's total (table 3). The so-called migration of the industry to the South is shown by the decline in spindles in New England from 68 percent to 22 percent of the total during the same period. Over three-fifths of the spindles in the South in 1939 were in the Carolinas, reflecting the tendency of the mills to concentrate in the Piedmont while cotton cultivation moved steadily south and west. The growth of cotton textile manu-

[1] Classified as "active-producing" spindles for the years 1899 to 1929.

[2] Includes 413,032 spindles in other than cotton mills.

[3] Includes ring spinning, mule spinning, and doubling and twisting spindles in the cotton-goods industry; excludes those in other textile manufactures.

[4] Total includes 1,281,697 spindles (including some in Kentucky) which were not distributed by State or region.

factures in the South was characterized initially by production of the coarse and cheaper goods. Gradually, however, the southern industry turned more and more to the production of finer yarns and fabrics, and extended its operations to include dyeing and finishing.

Other textile industries developed (see tables 4 and 5). By 1939 one-half of all the wage earners in the country's hosiery industry were in the South, one-fourth in North Carolina alone. The South was quick to adapt its mills to the processing of synthetic fibers. Between 1929 and 1939 the number of workers engaged in the manufacture of silk and rayon in the Southeast increased fivefold; and in the latter year this region had one-fourth of the Nation's wage earners in the industry. The production of woolen and worsted goods, while still predominantly located in the North, exhibited a measure of growth in the South. In 1939 these branches of textile manufactures together accounted for 39 percent of the manufacturing wage earners and 22 percent of the value of manufactures in the Southeast, indicative of the preeminent position of the textile industry in this area. Textile manufacturing is relatively unimportant in the Southwest.

TOBACCO MANUFACTURES

Although the tobacco plant was cultivated at Jamestown as early as 1612, centuries passed before its local manufacture matched its role as an agricultural staple. Kentucky and the James River area of Virginia were early centers for the manufacture of pipe and chewing tobacco, and in Florida there appeared about 1850 an important cigar industry based on imports of Cuban leaf.

[1] Includes cotton broad woven goods, cotton narrow fabrics, cotton yarn, and cotton thread.

[2] Includes both full-fashoined and seamless hosiery.

[3] Includes dyeing and finishing of cotton, rayon, silk, and linen; excludes such processing of woolen and worsted goods.

[4] Includes tailored clothing, shirts, trousers, work clothing (not elsewhere classified), underwear, neckwear, and hats and caps.

[5] Includes products of logging camps, sawmills, planing mills, and plywood mills.

[6] Includes upholstered furniture, other household furniture, office furniture, public building furniture, laboratory furniture, partitions, and mattresses.

[7] Excludes processing of cottonseed in making cooking oils.

[8] Although the data are not separately available by States, thus precluding a regional breakdown, all establishments covered by the Census were located in the South. Consequently the total of selected industries in the South is greater than the sum of Southeast and Southwest.

[9] Includes products of pulp mills and paper and paperboard mills, and manufacture of paperboard containers and boxes, not elsewhere classified; excludes other converted paper products.

[10] Includes all products so classified by the Census, except fertilizers, cottonseed products, and naval stores, given separately above.

[11] Includes cement, lime, cut-stone, and concrete products.

It was not, however, until the discovery of the flue-cured North Carolina leaf and the introduction of cigarettes from Great Britain in the early 1860's that the foundation was laid for the industry's phenomenal expansion. The rapid growth of the industry culminated in 1904 in a trust which, after an adverse Supreme Court decision in 1911, was dissolved into the important companies which continue to dominate the industry.

The development of tobacco manufactures was highlighted by the steadily growing market for cigarettes. In 1939 nearly four-fifths of the value of tobacco manufactures in the United States, but fewer than one-third of the industry's wage earners, were associated with the cigarette branch of the industry. At the same time, 40 percent of the industry—in terms of value—was located in North Carolina, principally in large, highly mechanized cigarette-making factories around Durham and Winston-Salem, while Richmond, Va., and Louisville, Ky., were secondary centers.

THE PETROLEUM INDUSTRY

In the first decade of the twentieth century, the Nation's oil center moved from the pioneering Pennsylvania fields to Oklahoma and Texas, thence to California in the early twenties, and back to Texas in the early thirties with the discovery of the rich East Texas field. Since then Texas has steadily extended its lead as the major oil-producing State, alone producing since 1930 about 40 percent of the Nation's crude petroleum. In recent years, Louisiana has overtaken Oklahoma's early lead; these two States, with Texas and California, comprise the four leading producers in the industry. Since 1883 Kentucky has maintained small but steady production from its extension of the Pennsylvania field. In 1920 Arkansas entered into production, to be joined by Mississippi in the late thirties, while wild-catting continued in other southern States. The approximately 85,000 wage earners in the industry in the South in 1939 represented about half the workers in the industry.

This "black gold" is the hub of the Southwest's industrial life, providing income and employment for thousands not directly associated with the industry. Petroleum and its products not only supply about a third of the Nation's energy requirements; it is also a storehouse of organic compounds basic to a wide variety of chemical

TABLE 5.—*Proportion of Total United States Wage Earners and Value of Product in Manufacturing in Selected Industries Located in the South, 1939*

manufactures. The character of the industry's development—its rapidity, its wealth, and advanced technology—injected a powerful dynamic into the southern economy.

FOREST-PRODUCTS INDUSTRIES

In the last half century the South has been, except for the Pacific Northwest, the major source of timber and wood products in this country. At the turn of the century the lumber and timber industry was the largest industry in the South. The industry reached its peak in terms of the regional economy about 1909, when it engaged one out of every three wage earners in the South and produced half of the country's lumber. In terms of the industry as a whole, the South increased its proportion of the country's wage earners in the industry from 35 percent in 1899 to 48 percent in 1939. Some assurance of the industry's future is implicit in the fact that in 1938 the South had about one-fifth of the Nation's timber stand and, of greater significance, about three-fifths of its relatively scarce hardwoods.

The South also plays an important role in three major branches of the forest-products industry—the production of naval stores, the manufacture of furniture, and the production of paper and pulp.

Since colonial times the South has kept a near-monopoly of the naval stores industry. Destruction of the long-leaf pine of the Carolinas had placed Georgia and Florida in the forefront of the industry by the turn of the century, to be succeeded by Mississippi, Louisiana, and Texas as the industry moved south and west along the coast. Although the industry has declined precipitously since World War I, the late adoption of conservation measures and planting of the prolific slash pine assures continued supplies at the same time that chemistry has progressively exploited the versatile pitch.

Until about 1900 the furniture industry was located largely near high-grade woods obtainable in the Northeast and from the virgin forests of the Middle West. As these supplies dwindled, the hardwoods of the southern Appalachians provided the basis for a furniture industry which has grown steadily in both size and quality of product. In 1939 the South possessed a fourth of the wage earners in the industry.

The realization that greater advantage could be secured by processing inferior woods into pulp and paper than by converting them into shoddy lumber gave rise, along with other factors, to the growth of a new industry. Although still in its initial phases in 1939, the pulp and paper mills of the South employed a fourth of the wage earners in the industry.

THE FERTILIZER INDUSTRY

For several decades the South has produced and consumed well over half of the Nation's fertilizer. Various factors account for the regional concentration of this industry. The high cost of transporting the bulky, heavy product makes it advisable to locate near consuming areas; the light, sandy soil and heavy rainfall of much of the South, and cultivation of the same crop year after year, require heavy doses of chemical plant food; the necessary raw materials, particularly phosphates and sulphates, are readily available; and relatively small capital and simple skills are required to establish and operate a fertilizer plant.

COTTONSEED AND ITS PRODUCTS

The early disposal of cottonseed is epitomized in the words of one contemporary who remarked that cottonseed was garbage in 1860, fertilizer in 1870, cattle feed in 1880, and "table food and many things else in 1890." Subsequent development has further multiplied its uses to include products varying from margarine and smokeless powder to varnish and insulation board. The importance of such development is evident when it is realized that the cotton plant produces about 2 pounds of seed for each pound of lint. Since 1910 cottonseed has accounted for approximately a sixth of the farm value of the cotton plant, and is a strategic and often lone source of cash as a result of the practice of exempting cottonseed as security for crop loans. The industry has in general followed the westward course of cotton cultivation; in 1939 the Southeast had 51 percent and the Southwest 44 percent of the wage earners in the industry.

MISCELLANEOUS INDUSTRIAL DEVELOPMENTS

The preponderence in the South of the industries just described is witness to a want of variety in the region's manufactures. The existence of certain other industries making for diversification should, therefore, be noted.

Flour and grain mills are widely scattered throughout the Border States. Various food industries have developed to take care of the increasingly diversified agricultural products. Canning, baking, and beverages particularly deserve mention. Sugar refining is found in Louisiana; and in 1939 Kentucky's distilleries employed 40 percent of the wage earners in that industry.

At the turn of the century the South had about a fifth of the Nation's workers employed in blast furnaces, most of them in Alabama. Although the *relative* importance of the industry declined in the South with the increasing utilization of Lake ores, Birmingham became the center of a growing and progressive iron and steel industry. The iron furnaces not only supply modern steel works and rolling mills in the area, but also provide the basis for a substantial iron-fabrication industry; in 1939 Alabama produced about half of the Nation's cast-iron pipe. During World War II the expansion of Alabama's facilities to make iron and steel totaled about 68 million dollars.

The South's production of brick and tile has for several decades been roughly commensurate with its share of the Nation's total manufactures. For many years the quarries of Georgia and Tennessee have provided the basis for an important cut-stone industry. In this industry and in the production of lime and of cement and concrete products, the South had a fifth of the country's wage earners in 1939. The related manufacturer of pottery and glass products has not, however, made much headway.

The growth of the textile, petroleum, fertilizer, and other industries described above reflect in different ways and degrees the pervasive influence of chemical processes in the rapid development of southern industry. In the industries classified as "chemical" by the Census, the South had 22 percent of the wage earners in 1939. About a third of these were engaged in the manufacture of rayon and allied products, heavily concentrated in Tennessee and Virginia. The manufacture of paints, dyes, soaps, plastics, and industrial chemicals, established at various places, promoted the growth of those industries which best typify the advances being made by southern industry.

Industrial Developments During World War II

About a fifth of the Nation's 20 billion dollar wartime expansion of manufacturing facilities was undertaken in the South. The specialized character of this expansion is indicated by the fact that 47 percent of the wartime investment was for the production of aircraft, ships, ordnance, and explosives. Whether such industrial expansion can or will be available for peacetime production is one of the most challenging postwar questions facing the South.

During the war various southern areas became scenes of feverish industrial activity. Plants for making explosives sprang up all over the region, often in rural areas, with notable concentrations at Choteau, Okla.; Minden, La.; Milan and Kingsport, Tenn.; Louisville and Paducah, Ky.; Aberdeen and Flora, Miss.; Pine Bluff, Ark.; Wilson Dam, Ala.; Texarkana and Waco-McGregor, Tex.; and in the Roanoke-Radford area of Virginia. One of the plants of the atomic bomb project was placed at Oak Ridge, Tenn.

An avalanche of ships came down the ways at Wilmington, N. C.; Hampton Roads, Va.; Charleston, S. C.; Tampa and Panama City, Fla.; Brunswick, Ga., and from the primary Gulf Coast areas around Mobile and Galveston Bays. Large aircraft factories appeared in the Dallas-Fort Worth area; at Marietta, Ga.; Louisville, Ky.; Oklahoma City and Tulsa, Okla.; and Memphis, Tenn. Synthetic rubber plants located near Texas oil at the Houston-Galveston and Amarillo–Borger areas, with secondary production at Louisville, Ky., and Eldorado, Ark. Southern facilities for producing aviation gasoline, amounting to half the Nation's wartime expansion of such facilities, located at Houston-Galveston, Amarillo-Borger, and Beaumont-Port Arthur, Tex.; Ponca City and Beckett, Okla.; Baton Rouge, La., and other petroleum centers. Native bauxite ore fed the aluminum plant at Pine Bluff, Ark., and others in the heart of the TVA power region, while still other aluminum plants were built at Austin and Houston, Tex. The manufacture of various chemicals proceeded apace at scattered locations, and the region's production of textiles and tobacco products rose to new heights.

Despite remarkable achievements in war production, it is doubtful whether southern industry has advanced its prewar position in the national economy, when, with 28 percent of both the Nation's population and land area, it possessed 17 percent of the country's wage earners and accounted for 14 percent of the value of its manufactures. Over the past half century, however, the industrial growth of the region has been notable, and there is great promise for the future inherent in its ample power reserves, its forests and its variety of mineral resources, its kind climate and topography, and the aspirations and native ability of its people.

II.—Labor Supply in the South[1]

The economic and social well-being of the South depends both upon its human resources and upon the quantity and quality of its physical resources. An examination of migration, population, and labor-force characteristics, which the war has affected but not fundamentally altered, is basic to any analysis of the economic position of labor in the South and of the outlook for economic development in the region.

Migration

Perhaps the most striking aspect of the labor-supply situation in the South is that the region not only provides labor for its own factories and farms, but it also contributes substantially to the labor supply of other regions of the Nation. The natural rate of population increase is considerably greater in the South than in the remainder of the country, owing to the higher fertility in the predominantly rural South than in the North and West. The pressure of population on economic opportunities in the South has been such, however, that large outward migration has taken place. During the 1920–30 decade, the number of migrants leaving the South exceeded the number entering by an average of 130,000 a year.[2] During the depression of the 1930's, when job opportunities in northern and western cities were at low levels, the net out-migration continued but reached only 100,000 a year. With the growth of the defense program, and then of the war production program, the annual rate stepped up to the unprecedented figure of 300,000.

Perhaps the most important single factor in increasing the rate of out-migration was the growth of job opportunities in the North and West: in the 1940–43 period more than 80 percent of the contracts for war products were let in these regions, in the cities where industry has long been concentrated. The thousands of jobs which these contracts opened up had to be filled in part by drawing workers from the Southern States. Outward migration from the South continued, in spite of the letting of contracts and the building up of war facilities within the region.

Except for the fact that movements were accelerated and were over longer distances, wartime migration followed the same general pattern that prevailed in peacetime years (table 6). If the 48 States and the District of Columbia are ranked according to percentage of net migration in 1935–40 and 1940–45, the 13 Southern States are found at approximately the same position for the later period as for the earlier. Thus, if we call the State with the greatest net in-migration number 1 and the State with the greatest net out-migration number 49, Arkansas is 44th on the list in 1935–40 and 45th in 1940–45. Most of the 13 States either maintained the same place on the list or dropped somewhat lower on the list because of net out-migration. Only 3 of the Southern States—Alabama, Tennessee, and Texas—moved up on the list in the direction of relatively less out-migration. The 13-State area—and every State in it, except only Florida and Virginia—continued to lose population to other areas.

---

[1] Prepared by Sophia C. Mendelsohn and Lester M. Pearlman of the Bureau's Occupational Outlook Division.

[2] Except where noted, the term "South" as used in this section refers to the 13 States of Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia.

[2] Civilian migration only.

As before the war, the South had a net loss in its wartime population exchanges with other regions (table 6 and chart 1). Of the 1,600,000 migrants who left the South between Pearl Harbor and March 1945, about 1,000,000 went to the North and 600,000 to the West.[3] In return, however, the South received only 600,000 persons from the North and 100,000 from the West—a net loss of 400,000 to the North and 500,000 to the West.

Internal migration in the South during the war also reached record magnitudes. Gross intrastate migration [4] in the region amounted to 3,200,000 between December 1941 and March 1945, while movements

between States within the region during this period totaled 1,600,000 (table 7). This reflects a movement from farms to cities during the war which is as striking as that from the South to other regions of the country. In fact, migration from the South was in large part a reflection of the shifts from rural to urban areas. For the United States as a whole, the net loss to the farm population through movement of civilians from farms averaged 900,000 per year in the period 1941 to 1945, compared with only 375,000 during the depression decade of the thirties and 630,000 in the twenties.[5] Evidence of the fact that migrants from the rural South not only went to cities in the North and West but also to southern cities is found in the large population gains registered in industrial areas such as Mobile and Houston.[6]

There is one particular implication in interregional migration to which attention should be called. The outward migration has provided other areas with workers who have been carried through the years of childhood, have been educated, and have in many cases received some work experience in the South (table 8 and chart 2.) After passing their early years in the South—unproductive ones in terms of their immediate contribution to the output of the region—they then move to other areas which can reap the fruit of this nurture and training. Data for the 1935–40 period indicate that of those who left the

South in that period, about three-eighths in the 25–34 age group had a high-school education or better, and six-sevenths had an eighth-grade education or better. As has been indicated, this give and take between areas works both ways, with migrants and capital from other areas entering the South, but, on balance, the South has been making a contribution to the other richer parts of the country.

A smaller percentage of Negroes left the South for other regions than was the case among whites, but there were so few colored persons entering the South from other regions that the South lost proportionately more Negroes than whites in the give and take of population between 1935 and 1940. Thus, Negroes accounted for one-third of the *net* out-migration from the South even though they made up one-fourth of the total southern population. Information on the extent of migration of nonwhites during the war is limited. Some evidence of migration of Negroes to the West, however, is found in the fact that the Negro population in five congested production areas on the West Coast more than doubled between 1940 and 1944.[7]

POSTWAR PROSPECTS FOR MIGRATION

What are the likely postwar trends with respect to migration of the South's population and labor supply? The answer to this question must necessarily be a conditional one. Migration will be heavily cut down if any large-scale industrialization program, drawing on the new war-built plants and on the skills of the wartime force of semiskilled and skilled factory workers, should develop vigorously in the South. But even under this assumption it is likely that migration from the South will be larger than migration to the South. There has been a long-term stability in the geographic distribution of employment opportunities which even the war did not fundamentally alter. The fast-growing population in the South, confronted with relatively low job opportunities and security, will continue to provide workers not only for its own industries but for those in other areas. Under conditions of fairly high employment, for example, job opportunities in New England, in the East North Central areas, and in the Pacific region are likely to be more favorable than in the South, so that migration from the South to these areas is bound to occur. Under conditions of full employment, migration is likely to be even more pronounced, for migration is a necessary step to full employment, given the differences in birth rates and industrialization which now exist and will probably continue to exist between different regions in our country. Only if severe depression were to set in would there be much likelihood of a reversal in the pattern of prewar and wartime migration.[8]

It is not likely that this generalization will be contradicted by the movement of returning servicemen. Surveys made by the War Department in 1944 [9] indicate that on the basis of their plans at that time, 15 in 100 of the soldiers who came from the South are likely to seek employment in the North or West after the war. This means that these States will be losing the potential services of many able-bodied and trained workers who could contribute effectively to the well-being of the Nation by developing the resources of the South. This trend forcibly suggests how essential is the study of the many plans and factors which relate to the greater industrialization of the South.

---

[8] Detailed analysis of changes in the labor force and postwar prospects for each of the Southern States appears in the article State and Regional Variations in Prospective Labor Supply, in Monthly Labor Review, December 1946.

[9] See Postwar Migration Plans of Army Enlisted Men, in The Annals of the American Academy of Political and Social Science, May 1945.

Trained and able-bodied labor is just as much a productive asset as a mine, a stand of timber, or 40 acres of fertile farm land. One of the South's major problems is how best to utilize this immensely valuable productive asset.

Population and Labor-Force Characteristics

In 1940, 37 million of the Nation's 132 million people lived in the 13 Southern States. Except for Texas, which accounted for over 6 million persons, and North Carolina, with 3½ million, each of the other 11 States had populations which ranged roughly between 2 and 3 million persons (table 9). The labor force or working population numbered some 14 million and, being drawn from the population 14 years of age and over, was distributed among the States in much the same fashion as the total population (table 10).

TABLE 9.—*Geographical Distribution of the South's Population, 1940, by Color and State*[1]

[2] Consists of persons 14 years of age and over either employed or unemployed.

POPULATION AND LABOR-FORCE GROWTH

Labor-force growth is in large measure a function of population growth. The rise of the American labor force from about 1 million in 1790 to 53½ million in 1940 is essentially an outcome of the increase in the population of working age—from about 2 million to 101 million over the 150–year period. Thus, between 1920 and 1940, population growth caused the southern labor force to expand at a greater rate than that of the North but at a lower rate than that of the West.

	Percent increase, 1920–40	
	Population	*Labor force*
South	20. 2	25. 0
North	16. 3	20. 0
West	35. 9	36. 7

In the absence of interstate migration, however, the South would have experienced by far the greatest rate of population growth, and, thereby, of labor-force growth. As the following tabulation indicates, the South has consistently been the region of highest fertility in the Nation:

	Net reproduction rate[1]	
	1905–10	*1935–40*
South	161	118
North	122	87
West	117	94

[1] Net reproduction rate of 100 means that each generation would just replace itself if birth and death rates of a given period were to continue indefinitely, and if there were no net migration.

This greater fertility is largely a reflection of the predominantly rural character of the South and of the fact that the proportion of nonwhite persons in its population is higher than in the North or West (table 11). High fertility is characteristic of rural residents and of nonwhites. More than 65 percent of the people in the South lived in rural areas in 1940; in the other regions of the country, the proportion was less than 40 percent. Similarly, 1 in every 4 persons in the South is nonwhite, in contrast to a ratio of less than 1 in 25 for the other

TABLE 11.—*Regional Distribution of the Population, 1940, by Residence and Color*[1]

Region	Residence				Color		
	Total	Urban	Rural nonfarm	Rural farm	All classes	White	Nonwhite
	Number (in thousands)						
South	37, 013	12, 873	8, 616	15, 524	37, 013	27, 651	9, 362
North	76, 120	51, 005	13, 571	11, 544	76, 120	73, 207	2, 913
West	13, 883	8, 128	3, 427	2, 328	13, 883	13, 349	534
	Percentage distribution						
South	100. 0	34. 8	23. 3	41. 9	100. 0	74. 7	25. 3
North	100. 0	67. 0	17. 8	15. 2	100. 0	96. 2	3. 8

regions. It should be noted, however, that even within the same residence and color groups, fertility is higher in the South than in the rest of the country.

As shown earlier, a fast-growing population pressing upon relatively limited economic opportunity has resulted in large-scale migration from the South in periods of depression as well as prosperity. The South will continue to export labor as long as its abundance of labor supply is not matched by opportunities for employment.

POPULATION CHARACTERISTICS AFFECTING LABOR-MARKET PARTICIPATION

The effect of the South's higher fertility can be seen clearly in the fact that its population and labor force are comparatively young. This is the case in spite of heavy out-migration of young and middle-aged persons from the South. The median age of the population of the South in 1940 was 25 years in contrast to 31 years in both the North and West. Approximately 52 percent of the South's labor force was under 35 years of age compared to 46 percent in the North and 44 percent in the West.

In addition, there are significant regional differences with respect to labor-market participation within each age and sex group. Although nearly all able-bodied men aged 25–54 years are in the labor force in every region, the work force of the South has relatively more young boys and older men, as shown in table 12. In the case of the youngsters, this is a reflection of the fact that rural youths can more readily enter the labor force than urban youths and of the related fact that southern youngsters leave school at a relatively early age. Only one-third of the southern adult population in 1940 attended school beyond the eighth grade. This relatively low proportion might be expected because of the South's predominantly rural character and because of its large nonwhite population, but even in each separate residence and color group the educational level in the South is lower than in other regions.

Unpaid family work on farms draws large numbers of southern youth into the labor force. Nearly one-third of the teen-agers in the

TABLE 12.—*Age Composition of the Male Labor Force, 1940, by Region* [1]

Age group	Number (in thousands)			Proportion in the labor force [2]		
	South	North	West	South	North	West

[2] Labor force as a percentage of population in each age group.

South's 1940 labor force were unpaid family workers in contrast to one-eighth in the North and one-tenth in the West.

The main reason that southern men retire from work at a later age than other men is that a greater proportion of them are engaged in farming, which is typically a family enterprise. As a farmer reaches old age his children or hired help take over the heavier burdens while he continues to work around the farm. In industry, on the other hand, a worker is often forced out of the labor market when he reaches an age at which he cannot compete with younger men. Other factors causing men to work to later ages in the South are the generally lower income levels and the absence of social-security coverage in agriculture.

In the South, nearly one woman in four works or seeks work outside the home. This rate of labor-market participation is slightly lower than that in the North and on a par with that in the West.

Residence and family characteristics of southern women serve to reduce the number working outside the home. The fact that relatively more women in the South live in rural areas has acted to lower the proportion in the labor force. Women in rural areas do not participate in the labor force to the same extent as urban women, principally because there is not much opportunity for any work except farming, where women are employed for the most part only during the peak planting and harvesting seasons. Moreover, farm women generally have more household responsibilities and perform many chores of the type which do not occur in nonfarm households. One out of every three women in urban areas in 1940 worked or sought work outside the home, compared with corresponding ratios of one in five for rural-nonfarm districts and one in eight for rural-farm areas.

In addition, the fact that the South has proportionately more married women and more young children per family has a tendency to keep women out of the labor market. Most women do not continue to work outside the home after marriage, and most of those who do continue to work quit after they have children. For example, among women aged 18–34 in 1940, approximately 67 percent of the single women were in the labor force, compared with only 31 percent of the married women without children, and 8 percent of the married women with children under 10 years of age.

Color composition works in the opposite direction since nonwhite women work or seek work (mostly in domestic service) to a greater extent than do white women. Thus, when farm and nonfarm women are compared separately, it is found that the rates of labor-force participation for the South are higher than the rates for corresponding groups in other regions.

	Percentage of female population 14 years of age and over in the labor force, 1940, in—		
	South	*North*	*West*
All women	24. 2	26. 2	23. 8
Urban areas	35. 1	30. 5	28. 4
Rural nonfarm areas	22. 4	20. 0	18. 1
Rural farm areas	13. 2	10. 7	12. 0

Here, then, are the dominant characteristics of the South's labor force: (1) Except for the effect of migration, the South has the greatest potential rate of labor-force growth in the Nation. (2) Nonwhite workers comprise a relatively large proportion of the South's labor force. (3) There is a predominance of rural workers. (4) The proportion of the labor force concentrated in the younger age groups is greater than for other regions. (5) Southerners leave school earlier to go to work and retire from the labor force at later ages than people in the North and West. (6) In general, the South has relatively fewer women working outside the home than the North, as a result of rural residence and responsibility for the care of larger families. This is true despite the greater labor-market participation of nonwhite women.

III.—Employment in Southern Manufactures [1]

World War II expansion and subsequent contraction of the number of persons employed in manufacturing industries in the South closely paralleled the movement of manufacturing employment in the United States as a whole.[2] In 1939, just as hostilities were beginning in Europe and before the effect of lend-lease production was felt in this country, factory employment in the South approximated 1,658,000 and in the United States as a whole, over 10,000,000 (tables 13 and 14).

By January 1943, at the end of 1 year of full-scale war production, employment in the Southern States had increased 60 percent as compared with about a 64-percent rise for the Nation. By November 1943—the wartime peak in manufacturing employment for both the Southern region and the United States—those employed in the South numbered 2,836,000. The gain was 71 percent as compared with a national increase of about 76 percent over the prewar period.

An even greater similarity of trend was apparent in the later war years. In August 1944, both the South and the United States as a whole had an employment level 68 percent above that of 1939. By VJ-day, in spite of cut-backs and contract cancellations, factory employment for both the United States and the Southern States was about 50 percent above the prewar level.

Immediate contraction of employment at the war's end was not as severe in the South as in the Nation as a whole. The 2,248,000 workers in the South in September 1945 represented a decrease of less than 9 percent between August and September compared with a national decline of over 12 percent. Also, at the time of the postwar low, in February 1946, the South's factory employment was 32 percent above prewar as compared with only 24 percent in the Nation.

Following the postwar low, the South did not gain as rapidly as the Nation. August 1946 manufacturing employment of 2,315,000 was 40 percent above the prewar level, whereas the national increase was 44 percent.

---

[1] Prepared in the Employment Statistics Division of the Bureau's Employment and Occupational Outlook Branch by Eleanora H. Barnes under the direction of Clara F. Schloss.

[2] In this section, "employment" is construed as total manufacturing employment; that is, covering all production and nonproduction workers in private manufacturing industries.

The term "South" refers to the 13 States of Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia. Detailed estimates of factory employment by State and by industry are available on a monthly basis as part of the Bureau's expanded program in the field of employment statistics.

[1] Prewar estimates for Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, and Virginia are based on unemployment compensation data of the Bureau of Employment Security of the Federal Security Agency, average for the third quarter of 1939. Prewar estimates for Kentucky are based on unemployment compensation data, annual average for 1939. Tennessee estimates are based on unemployment compensation data, average for the third quarter of 1940. Arkansas, Louisiana, Oklahoma, and Texas prewar estimates are based on Census Bureau data for 1939 and are not strictly comparable with data for later periods.

[2] Month of wartime peak employment in the South.

Position of the South in the Nation's Economy

Despite the increase in industrialization during wartime, the relative position of the South in the Nation's economy remained approximately the same (table 15). During the period of peak wartime employment, southern industry expanded slightly less rapidly than in the United States as a whole, but by 1945 it had again returned to the prewar ratio where it remained. The South has not materially increased its share of the Nation's total employment. However, the anticipated 17-percent increase in the South's labor supply from 1940 to 1950, coupled with the war-induced greater diversification of industry, and larger reservoir of skilled workers, all give promise of a brighter industrial future.

Major Components of Southern Manufacturing

In the prewar period, the nondurable goods group, heavily weighted by the textile industry, furnished over two-thirds of the employment in the South. Expansion in war industries—primarily shipbuilding and aircraft—increased the relative importance of employment in the durable-goods group to about 46 percent of total in 1943; but by 1946 the prewar ratio was again approached. While the relatively stable nondurable-goods industries employed more workers even during the war peak than the durable-goods industries, the more than doubling of durable-goods employment and subsequent deflation governed the over-all pattern of employment.

Major Industry Groups—South Compared With the Nation

The similarity of industrial development in the South and the Nation during the war years tends to minimize the possibility that expansion of war facilities in the South resulted in a permanent relative gain in manufacturing employment. There has, however, been a broadening of the importance of southern industries in the Nation's

[1] Since January 1943, the Bureau has been receiving employer reports covering total employment as well as production workers. Nonproduction worker estimates for each group have been based on the monthly changes shown by the nonproduction worker segment of these reports. Before 1943, various estimating methods were used to obtain total employment from the production worker series. For this reason, the series, in some groups, may not be consistent prior to 1943. Both production and nonproduction worker series have been adjusted to employment data made available annually by the Federal Security Agency.

[2] 8-month average.

[2] 8-month average.

[3] Not strictly comparable with later periods.

economy. In 1939, almost half of the workers in the lumber industry and over two-fifths of those in the tobacco and the textile-mill products groups were in the Southern States (tables 14 and 15). The southern sections of the petroleum, furniture, and chemical industries each employed about a fourth of the United States total for these industries. The only other really important industry was food processing which employed over a sixth of the United States total. At the 1943 peak, the South accounted for an even greater share of those employed in each of these outstanding groups with the exception of chemicals. In addition, such manufacturing groups as transportation equipment and paper also had over 15 percent of their employees located in the South and 8 of the remaining 11 smaller groups increased in importance.

Much of the diversification acquired during the war period was carried over into 1946. Whereas in 1939, 5 of the 20 major manufacturing groups had 5 percent or less of their employment in the South, only 3 were in this position in 1946. The southern industry groups that had always loomed large in the national economy continued to hold their own; the increased importance of many of the other industrial groups makes the South less vulnerable to economic disturbances. Such diversification makes for a healthier postwar situation.

Trend of Employment in the South, by Industry Group

War expansion caused many changes in the industry group pattern within the Southern Region. The largest group was textile-mill products which in 1939 furnished only slightly less than a third of all factory employment (table 16). The lumber and food-processing groups were next and together employed about a fourth of the total. Chemical products, furniture, apparel, and the iron and steel products groups accounted for another fourth.

By 1943, all groups showed aggregate increases in average employment varying from a few hundred in the automobile industry to a gain of 443,000 in the transportation-equipment group. The outstanding relative and aggregate increases occurred, of course, in transportation equipment; this group rose to second place in 1943 when it accounted for one-sixth of all workers. Because of the absorption of such a large part of the labor supply in transportation-equipment manufacture, the only other increases in this period were in such war-essential groups as iron and steel products,

TABLE 16.—*Manufacturing Employment in the South, by Major Industry Groups, for Selected Periods*

Industry	Employment (in thousands)					Percent of total				
	Prewar [1]	1943	1944	1945	1946 [2]	Prewar	1943	1944	1945	1946 [2]

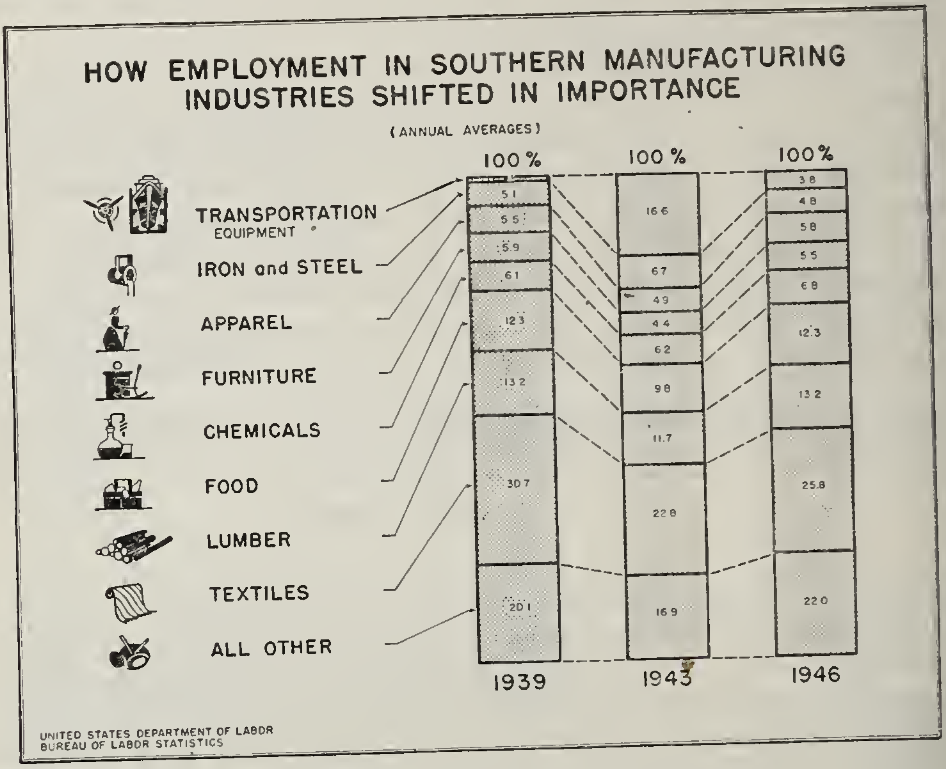
[2] 8-month average.

[3] Not strictly comparable with later periods.

the machinery groups, nonferrous metals, and chemical and rubber products.

In 1946, the aggregate average employment in all industry groups, except miscellaneous industries, was above the prewar level and for 10 of the major groups was above the 1943 levels. As regards total regional employment, the largest relative decrease between 1939 and 1946 was in textile-mill products—from 31 to 26 percent (chart 2).



Postwar Highlight in Southern Employment

A year after the war's end, the employment total of 2,315,000 for the South represented an over-all net decrease of 148,000 or 6 percent (table 17). Only six major groups—transportation equipment, electrical machinery, iron and steel, automobiles, chemical products, and machinery except electrical—employed fewer people in August 1946 than on VJ-day. Contractions in the shipbuilding and aircraft industries alone accounted for almost 70 percent of the gross decrease. Disregarding this expected sharp contraction in the transportation-equipment group, the employment rise for the year is about 3 percent.

Immediate reductions in employment in the 1 month following VJ-day amounted to an over-all loss of 215,000 workers, or 9 percent of all employment. The most severe cut occurred in the transportation-equipment group in which almost 40 percent were laid off.

TABLE 17.—*Estimates of Total Manufacturing Employment in the South for Selected Months, by Industry*[1]

[In thousands]

Industry	Prewar employment [2]	January 1943	November 1943 [3]	August 1945	September 1945

[1] Estimates for industry groups are adjusted to levels indicated by 1944 unemployment compensation data of the Bureau of Employment Security of the Federal Security Agency.

[2] See table 13, footnote 1, for date and source of prewar data.

[3] Month of wartime peak employment in the South.

[4] Not strictly comparable with later periods.

Employment was reduced by about one-third in the iron and steel, electrical machinery, and automobile groups; the chemical-products group declined by 15,000 or more than 8 percent. An offsetting seasonal gain of over 4 percent in the food processing industry and slight increases in the tobacco, paper, and printing industries were the only upward tendencies.

Owing to the Nation-wide steel strike, employment in the South, as in the Nation, reached a postwar low in February 1946 despite the fact that many industries were already well established in their reconversion adjustment. Only the iron and steel, machinery, transportation-equipment, automobiles, chemical products, tobacco, and the seasonally affected food groups continued at a lower employment level than in the September 1945 cut-back period.

From the February low to August 1946, declines were limited to the transportation-equipment and chemical-products groups. As the employment drop for the chemical products group was partially seasonal, the major single retarding factor in the recent employment upswing in the South was the continuing contraction in shipbuilding and aircraft.

Postwar Highlights—South and United States, by Industry Group

The employment changes in industry groups in the South in the first year of peace were somewhat akin to those in the United States. For both the United States and the South, iron and steel, the machinery groups, transportation equipment, and chemicals showed employment losses. But most of the percentage decreases were less severe nationally than in the region. In nine groups, national gains were greater than those in the South. In five—nonferrous metals, leather, miscellaneous, paper, and printing and publishing—the South showed greater proportionate increases over the period than the Nation. Although the South's automobile industry was small, it was the one industry in the region which showed an opposite trend to that in the Nation.

Employment in Southern States

The manufacturing economy of component States of the Southern Region was affected in varying ways by wartime expansion. Expansion of plant facilities in the less industrialized States brought later, and for the most part, proportionately greater peak employment. As the war ended, many of these shifts in importance and in industrial pattern were not maintained.

TRENDS—STATES COMPARED WITH REGION

In the prewar period, North Carolina—with an average employment accounting for about 18 percent of all manufacturing workers in the

Southern Region—was the most highly industrialized State. Georgia with nearly 12 percent and Tennessee with over 10 percent were next in importance. Texas with 10 percent was a close fourth (table 18).

TABLE 18.—*Manufacturing Employment in the Southern States by Region and by State, for Selected Periods*

Region and State	Employment (in thousands)					Percent of total				
	Prewar [1]	1943	1944	1945	1946 [2]	Prewar	1943	1944	1945	1946 [2]

Texas	166.4	424.8	425.0	364 5	302.5	10.0	15.3	15.4	14.8	13.5

[1] See table 13, footnote 1, for date and source of prewar data.
[2] 8-month average.

By 1943, interstate relationships had changed. The average number of persons in manufacturing in Texas had more than doubled, and Texas was the leading manufacturing State in the region. With an aggregate gain of even less than a third, North Carolina dropped to second place. All States experienced some wartime expansion, but increases were proportionately smaller in Georgia, Tennessee, South Carolina, and Virginia (in addition to North Carolina) in the southeastern group of States than elsewhere. For all these States, the relative decrease in industrial importance was continued into the postwar period.

In addition to Texas, all of the other Southwestern States—Oklahoma, Louisiana, and Arkansas—and Florida and Alabama in the Southeast, had a greater share of regional employment in 1943 than in 1939. Further gains for Texas, Oklahoma, and Louisiana occurred in 1944, while in Arkansas the rise continued even in 1945; Kentucky and Mississippi had a greater proportional employment in 1946 than at any other time.

The States of the Southwest were less industrialized before the war than those in the Southeast. The influx of war facilities and contracts raised the proportion of regional employment in the Southwest from about 20 percent in 1939 to 28 percent in 1944. On the basis of the record for the first 8 months of 1946, the Southwestern

States have declined from this peak position, but they still employ a fourth of the South's factory workers.

Based on the same 8-month average in 1946, each of the States in the Southwest and Alabama, Mississippi, and Kentucky in the Southeast showed proportional increases over the 1939 relationship. It seems, therefore, that the Southwest and some of the smaller industrial States of the Southeast have maintained their increased share of southern manufacturing employment.

OUTSTANDING INDUSTRIES IN THE SOUTH

The considerable importance of the textile-mill products group in the manufacturing economy of the South is well known. Also important are lumber, food processing, chemicals, apparel, furniture, iron and steel, and—during the war and postwar period—transportation equipment. Contrary to a general impression, the tobacco industry in the South actually accounts for only about 2 percent of total manufacturing employment. However, this industry is significant in furnishing work in such States as North Carolina, Virginia, Florida, and Kentucky.

Textile-mill products.—The largest single industry group in the South—textile-mill products—employed about 30 percent of all factory workers in the prewar period and about 25 percent of all southern industrial workers in 1946 (based on an 8-month average). Employment in the group increased 24 percent from 1939 to the peak year of 1943 and, despite declines after 1943, rose over 13 percent between 1939 and 1946; most States participated in the increase.

Little change occurred in the relative standing of the States in the industry. In 1946, about 213,000 or well over one-third of the employment was located in North Carolina. South Carolina with 120,000 ranked second and Georgia with 103,000 ranked third.

Although textile-mill products (with cotton textiles as the primary industry) formed the largest single employing group in the entire southern region, 96 percent of the group employment was concentrated in only six States—Alabama, Georgia, North Carolina, South Carolina, Tennessee, and Virginia.

Lumber and timber basic products.—Lumber—the second larges industry group in the South—accounted for about an eighth of thos employed in the region both in 1939 and after the war. Distributio was fairly even among 11 of the 13 Southern States in 1939; Oklahoma and Kentucky had only small numbers in the group. Alabam ranked first in 1939 with 27,000 workers or about an eighth of th industry total. North Carolina had 25,000 and Mississippi 23,00 persons so employed and the remaining 8 States had from 14,000 t 20,000.

The industry—comprising primarily logging camps and sawmills—increased almost a half in size by the peak year 1943 in spite of labor recruitment difficulties; 1946 employment still exceeded the prewar level by over a third. Only Florida and Oklahoma showed decreases for the entire period. Alabama alone of all the States showed a gain in 1946 over its war peak average. Employment in this State in the lumber group totaled 42,000 workers, a slight relative increase. Georgia, which ranked eighth in 1939, had more than doubled its employment and risen to second place in the industry in 1946. In the latter year, 11 percent of the total lumber group workers were in Georgia.

Food.—Food processing was the third outstanding industry of the South and a little over an eighth of all workers were in this group in both 1939 and 1946. The group was of considerable size in all States in the South. However, in 1939, one-fifth of its workers were concentrated in Texas and one-eighth in Louisiana.

Between 1939 and 1946, food-processing employment had increased one-third and all States shared in the gain. In Texas, the rise was over a half to 59,400 and in Louisiana more than a third to 34,500. Kentucky, Arkansas, and Louisiana each employed more food-processing workers on an average in 1946 than at any other time in the entire period.

Chemicals and allied products.—The chemical-products group accounted for 100,800 workers in 1939—slightly more than 6 percent of regional employment. With many industries within the group requiring new plant facilities for full war production, the peak of 189,600 did not occur until 1945. By 1946, employment had decreased but was still 52 percent above the prewar level.

Owing to the diversity of the industries in the group,[3] it is not practicable to generalize on the causes of regional changes. However, the changes in Tennessee and Virginia, which together comprised about 45 percent of the regional group employment in 1939 and 52 percent in 1946, strongly influenced the over-all pattern.

Employment in the chemical group in Tennessee rose from 23,400 in 1939 to a peak of 61,500 in 1945. In 1946, the number was almost double the prewar total for the State and had risen from 23 to 30 percent of the regional total for the group. The development of the Oak Ridge atomic bomb plant and increases in the production of industrial chemicals were mainly responsible.

In Virginia, the number rose to 34,000—about a 54-percent increase—between 1939 and 1946. Production of rayon fibers furnished the largest segment of employment in the group throughout the entire period, but its importance was reduced during wartime when the production of industrial chemicals increased.

---

[3] Fissionable materials, explosives, industrial chemicals, synthetic rubber, rayon fibers, animal and vegetable oils, and fertilizer make up the group.

Apparel and other finished textile products.—The fifth largest industrial group in the South was apparel, which employed 129,400 workers making up 6 percent of regional employment in 1946. The gain was 43 percent from the prewar level. Georgia accounted for about a fifth of the South's apparel workers in the prewar period, and only about a sixth by 1946. Texas had first place in 1946 with an employment total of 22,000, and Tennessee averaged 20,100 workers. These three States together accounted for approximately half of the total workers in the apparel group.

Furniture and finished lumber products.—The furniture products group averaged 122,700 workers in 1946—only slightly fewer workers than the apparel group. The 1946 level was about a fourth higher than before the war and was the peak for the entire period covered.

In 1946 furniture plants in North Carolina (producing primarily household furniture, mattresses, and bedsprings), with 28,300, employed 23 percent of the southern group total. Virginia and Tennessee ranked second and third in 1946 and with North Carolina comprised nearly half of the furniture group.

Iron and steel products.—The iron and steel products group accounted for about 5 percent of total manufacturing employment in the South in 1939; the percentage rose to 7 in 1944 when wartime expansions more than doubled such employment. After the war ended, iron and steel plants retained approximately the same proportion of workers as in the prewar period. The four States of Alabama, Tennessee, Texas, and Kentucky had over three-fourths of the regional total in the iron and steel group in 1946. Alabama ranked first, with almost 42 percent of the total, in 1939; but by 1946 the percentage had dropped to 34. In Texas, the number of persons so engaged more than doubled between 1939 and 1946, and the proportion increased from 7.7 to 14.5 percent of the regional group.

Transportation equipment (except automobiles).—Employment in the transportation-equipment group—primarily aircraft and shipbuilding industries—amounted to only 1 percent of the total for manufacturing in the South in 1939. Tremendous war expansion of these industries, from 18,000 in 1939 to 468,000 in 1944, raised the proportion to 17 percent. By 1946, the total had receded to less than 4 percent of regional employment.

In the prewar period, Virginia had the only sizable transportation-equipment group in the South, employing 9,700 or over half of such workers in the region. By 1944, the Virginia total had tripled, but because of the tremendous expansions in all but one of the Southern States, Virginia ranked seventh, following Texas, Florida, Georgia, Louisiana, Alabama, and Oklahoma. But in 1946, only Texas—with 27 percent of the total in this group—outranked Virginia.

CONTINUED EMPLOYMENT EXPANSION

Continued expansion in southern manufacturing employment is indicated by estimates for both September and October 1946. Between August and October 1946, 20,000 workers were added. Florida, Virginia, and Alabama absorbed most of these workers by adding about 5,000 or more each in this 2-month interval. Only 4 of the 13 Southern States failed to share in the increase.

IV.—Income in the South[1]

Variations in income among the States are due to differences in the natural resources, capital equipment, and productive abilities of the different populations. The possession of abundant capital and natural wealth in relation to population usually constitutes a basis for a high level of income and well-being. Where such resources exist, the States can support adequate programs of public education, health, and general welfare. All the people are the beneficiaries of such programs, particularly those in the lower-income groups. On the other hand, the level of income tends to be low where resources are naturally meager or have been depleted, where capital equipment is relatively small, and where the population is not generally skilled in industry. As a result, State revenues are low, and public functions are likely to be limited. In such areas, a change in the balance between population and resources will tend to occur. In the South,[2] this process has taken primarily the form of out-migration[3] and of industrialization through the use of capital accumulated in the region and brought in from the outside.

Human welfare cannot by any means be measured entirely in terms of money income. Estimates of aggregate income payments[4] and their components, however, can be used roughly to describe the economic status of the population as a whole, and per capita income[5] to indicate the average status of the individual. Such estimates are available for the individual States, and comparisons can therefore be made between the Southern States and the rest of the country. Comparisons are desirable, as the concept of "income level" is relative.

Differences in income level between the South and the remainder of the country reflect, in part, differences in the character of economic activity. Agriculture, of course, is relatively more important, and manufacturing less important, in the South than elsewhere. Moreover, there are important differences between agriculture as carried on in the South and in other areas: farms in this region average fewer acres, capital equipment is smaller, and productivity per man is lower. The structure of manufacturing industry (kinds of industries, proportions of various labor skills employed, etc.) differs substantially in the southern and nonsouthern sectors of the economy. These variations in types of economic activity help to explain why the general level of per capita income in the South, even in 1945, was low relative to the national level.

---

[1] Prepared by Solomon Shapiro of the Bureau's Labor Economics Staff. The State income data used in this section have been published or made available by the National Income Division of the Office of Business Economics of the U. S. Department of Commerce. The cooperation of this Division is gratefully acknowledged.

[2] The "South" is used to mean the nine Southeastern States: Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, and Mississippi; and the four Southwestern States: Arkansas, Louisiana, Oklahoma, and Texas.

[3] See the article Labor Supply in the South, p. 16 of this bulletin.

[4] State income payments represent income received in the various States by individuals, from payers either within or outside the State. These payments include certain "nonproductive" receipts which are included in money income, such as social-security benefits and relief payments. They exclude certain items of income, like business savings, which accrue to, but are not received by, the population. Certain imputed items, such as products consumed on the farm, are also included.

[5] Per capita income payments are derived by division of total income payments by total population, excluding armed forces and civilians outside the continental United States.

While per capita income in the South is low compared with the average for the country, a definite and encouraging upward trend has, however, been evident in recent years. This trend reflects the changing structure of the southern economy resulting from a decline in the relative importance of agriculture, and as a counterpart, an increase in manufactures. Per capita income in the Southern States rose from 55 percent of the national average in 1929 to 69 percent in 1945. Between these dates income in the aggregate had more than doubled in the South, and the region's share of the country's total income had increased appreciably.

A portion of the gain in relative income position grew out of the war. In meeting its war needs, the Nation found in the Southern States a large pool of manpower and a convenient location for many military installations as well as war manufacturing plants. As a result, income payments to individuals in the South increased at a faster rate than in the other States during the war years. It is difficult to tell at this time to what extent the gains of the war years will be permanent.

This section presents estimates of per capita income, average annual wages, and aggregate income payments and their components in the South and the rest of the country. Changing relationships since 1929, and particularly during the war period, will be indicated.

Per Capita Income

TOTAL POPULATION, INCLUDING MILITARY

The marked differential in incomes between the South and other regions of the country is being reduced. Since 1929 per capita income in the Southern States has steadily drawn nearer to the national average. The per capita income of $371 in 1929 was only 55 percent of the national average. In 1940, the per capita income of $340 was 59 percent of this average. In spite of a somewhat greater relative ncrease in population between 1940 and 1945, per capita income in the Southern States was $797 in 1945, 69 percent of the national average (table 19).

---

[1] Per capita income payments are derived by division of total income payments by total population (excluding armed forces and civilians outside continental United States). For residents of Virginia employed outside that State, income was transferred from the State of the recipients' employment.

[2] Source: U. S. Department of Commerce, Survey of Current Business, August 1946, and unpublished data.

Among the Southern States, the lowest per capita income has consistently been found in Mississippi, where in 1933 it was only $123, 33 percent of the average income in the country. However, this amount has steadily increased until in 1945 it was 48 percent of the country's average. For a considerable period, Florida has come closest to the national average in per capita income payments—being 71 percent of this amount in 1929 and rising to 87 percent in 1945. During the war years, both Texas and Virginia were around the 80-percent level.

CIVILIAN POPULATION

The inclusion of military pay rolls in total income served to increase southern per capita income during the war years, as average military pay was generally higher than per capita income to civilians in the South. It is desirable, therefore, to examine civilian per capita income by deducting wage payments to armed forces personnel (table 20).

TABLE 20.—*Per Capita Income Payments to Civilian Population, by Region, 1940–45* [1]

Region	1940	1941	1942	1943	1944	1945
	Civilian per capita income payments					
United States	$573	$694	$860	$1,050	$1,143	$1,158

[1] Source: U. S. Department of Commerce, Survey of Current Business, August 1946, and unpublished data.

This procedure somewhat reduces the per capita income in certain of the Southern States, particularly in the early years of the war, but in the other States where civilian average incomes were higher than military pay, per capita income was increased. The deduction of military pay lowered per capita income in the South from $555 to $539 in 1942, and from $797 to 791 in 1945.

Clearly, there was not sufficient difference between the levels of military and civilian income payments to change any of the important generalizations with respect to the relationship of the South to the rest of the country. The change, however measured, in per capita incomes in the Southern States between 1940 and 1945 more than matched the doubling of incomes in the rest of the country. As a consequence, per capita incomes in the South were appreciably nearer the national average at the end of the period.

Income Status of the Southern Worker

The per capita measures of income take cognizance of the changes in population and represent the income of the average individual—man, woman, or child. The aggregate measures of income, which will be presented later, are useful in showing the relationships of the various economic groups and the relative changes occurring in the economic position of these groups. Both measures fail to describe with any degree of precision the income status of the individual worker.

The ideal procedure for the purpose of describing earnings of typical workers would be to obtain average annual wages for all homogeneous groups of workers, broken down by State, industry division, occupation, sex, race, age, etc. It is unfortunate that data of this sort are not available. For most commercial and industrial workers, however, State unemployment-compensation tabulations can be used to show average annual wages and salaries in the major industries. The best available data for showing the status of farm workers in the various States are the farm wage rates compiled by the United States Bureau of Agricultural Economics.

ANNUAL WAGES IN INDUSTRY

The average worker in southern industry improved his annual earnings during the war in absolute terms and in relation to the average worker in the country as a whole. In table 21, the average annual wage per job covered by State unemployment-compensation laws are shown for seven major industries from 1939 through 1944. These average wages rose steadily in the South, from $1,016 in 1939

TABLE 21.—*Average Annual Wage Per Job*[1] *Covered by Unemployment-Compensation Laws, United States and the South, by Major Industry Groups, 1939–44*[2]

---

[1] Obtained by dividing total wages and salaries paid in covered employment in the various industries by the average employment in these industries. The latter figures are averages of 12 monthly figures, each of which is a total of the number of workers in the industry in the last pay period of the month.

[2] Source: United States data and 1944 data for the South derived from Federal Security Agency, Employment Security Activities, May 1946. Other years for the South are derived from data in the Social Security Yearbooks of the Federal Security Agency.

[3] Includes data for covered workers in agriculture, forestry, fishing, and establishments not elsewhere classified.

[4] Includes crude petroleum and natural gas production.

[5] Excludes railroads and other allied groups subject to the Railroad Unemployment Insurance Act.

to $1,798 in 1944, an increase of 77 percent. This compares with an increase of 69 percent for the country as a whole, from $1,360 in 1939 to $2,302 in 1944.

In 1939, average wage per job in the different industries in the South ranged from $849 in service to $1,592 in finance. By 1944, the averages had shifted in relative rank, but service was still lowest with $1,275, while contract construction was highest with $2,371. Averages in the Southwest were generally higher than in the Southeastern States. In mining, the presence of the high-wage petroleum industry raised average annual wages in the Southwest above the level of the country as a whole. In all the industries except mining, wages of the southern worker drew nearer to the national average between 1939 and 1944.

These estimates of annual earnings do not represent all workers, as in 1944 only about 70 percent of all wages and salaries in the country were paid to workers in industries covered by State unemployment-insurance laws. In the South, moreover, only about 55 percent of total wages and salaries were paid in covered industries. Among those excluded from coverage are farmers, farm workers, and domestic workers, and these groups form substantial proportions of the southern labor force. In addition, 10 of the 13 Southern States cover only firms employing 8 or more workers. Since average earnings of employees in the smallest firms tend to be relatively low, average annual wages of workers covered by unemployment compensation in the South are biased upward as compared with the rest of the country. Nevertheless, as a measure of wages in industrial and commercial establishments of other than very small size, such figures have significance.

It should be clear that the differentials in earnings measure variations in opportunity for employment as well as wage and salary differences, as more commonly understood. For example, average annual wages in southern manufacturing reflect the average return in wages to workers in those particular industries that happen to exist in the South. Similarly, average annual wages in manufacturing in the remainder of the country reflect the return to workers in a somewhat different industrial structure, utilizing, to some extent, other types of skills and other proportions of various grades of skill. Regional wage differentials as such are considered in a separate article.[6]

INCOME IN AGRICULTURE

Although agriculture has become relatively less important in the southern economy, the income status of the individual farmer and farm worker has considerably improved since the depression years. Migration of farm population has alleviated somewhat the pressure of population on the land. It enabled those who remained to improve greatly their position when the demand for farm products and farm prices increased in the prewar and war years. Average net farm income per farm in the South increased from $582 in 1940 to $1,708 in 1944. The threefold increase in net farm income during this period, although about the same as in the rest of the country, is more significant for the South. In this region, the greater rate of decrease in the number of farms and farm population led to larger average-sized farms which, with increased productivity, placed agriculture on a somewhat better economic basis.

---

[6] See the article Regional Wage Differentials, p. 56 of this bulletin.

The monthly composite wage rate of farm workers in the South increased from $21.20 in 1939 to $53.20 in 1944. This composite wage represents an average of four rates—monthly rates with and without board, and daily rates with and without board—weighted by the estimated number of workers receiving each rate. It is useful in showing the relative changes in wage rates in the South, which can be compared with the relative change in the index of farm wage rates for the United States. The index of farm wage rates (1910–14=100) was 123 for the country in 1939 and 315 in 1944. The increase of 151 percent in the composite wage rate for the South compares with an increase of 156 percent for the country as a whole.

Income Payments and Their Composition, 1929–45

Some indication of the broad economic changes which have taken place within the country since the high level of business activity of the late 1920's is obtained from the changing proportions of the types of income which compose total income payments. Table 22 and chart 1 show four principal kinds of income and their relative importance in the South and the rest of the country for the period since 1929.

The discussion which follows deals with relative shares of income and not with total amounts. Thus, the absolute amount of property income in the South increased materially between 1929 and 1945, although property income, as a share of total income, declined. Similarly, wage and salary payments more than doubled during this period, despite the fact that the proportions of such payments in the income total showed little change.

In the years prior to World War II, wages and salaries in the South represented somewhat less than 60 percent of the total income of the population. During the war, the large volume of military pay rolls, together with increased earnings and greater employment in industry, brought wages and salaries to 66 percent of total income in 1943. Toward the end of the war, with the "shipping out" of military personnel and the increasing importance of family allotments and mustering-out pay, the proportion of wages and salaries was reduced to

CHART I

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

its prewar relationship. In the other States, the proportion of income going to wage and salary earners has always been greater than in the South. This reflects the relatively greater number of industrial workers and smaller number of farmers and farm workers[7] in the States outside the South.

TABLE 22.—*Total Income Payments and Their Composition, the South and all Other States, 1929–45*[1]

The decreased importance of proprietors' income in the South which started in the depression years of the early 1930's continued throughout the war period. From 27 percent of total income payments in 1929, income to unincorporated business, including agriculture, declined to 23 percent in 1940 and to 21 percent in 1945. The relative increase in wages and salaries in the first part of the war and of "other income" toward its close, and the large decrease in the number of farm proprietors throughout the period, were important reasons for the smaller share of total income going to proprietors during the war. While this decline was taking place in the South, proprietors' income remained a much more stable component of the total in the rest of the country.

The proportion of income received from property, represented by net rents and royalties, interest, and dividends, has been decreasing throughout the country since 1929. The decrease received added impetus during the war with increased taxes, rent ceilings, and declining interest rates. In the South, income from property fell from 13 percent of total income in 1929 to 12 percent in 1940 and to 8 percent in 1945. The greater concentration of wealth in the rest of the country led to an even greater percentage decline in its proportion of property income.

---

[7] In 1940, farmers and farm workers represented 34 percent of the employed labor force in the Southern States, compared with only 12 percent in the rest of the country.

The "other" type of income payments became substantially more important in all parts of the country after 1929. In the thirties, the increase resulted from the large volume of relief and work-relief payments and social-security benefits. The latter became significant toward the end of the decade. With many dependents of military personnel living in the Southern States during the war, the inclusion of family-allowance payments and allotments made the category of "other income" relatively more important in the South after 1942. The inclusion of mustering-out payments to veterans in 1944 and 1945 raised the proportion still higher in the Southern States.

Aggregate Income Payments

Although per capita income in the South is still considerably below the national average, as indicated earlier in this section, income payments showed remarkable gains in these States during the immediate prewar and war years. Not only has the income level of the population been raised in absolute terms, but an increasing share of the Nation's total income has been going to these 13 States. In 1929, 15 percent of the country's total income payments went to the South. By 1940, this proportion had gone up to 17 percent, and by 1945 to 20 percent (table 23).

Each of the nine Southeastern States increased its proportion of total income payments between 1929 and 1945. To this group of

[2] Includes only payments to residents of the continental United States, therefore excluding pay of armed forces and Federal civilian employees stationed outside the country.

States in the aggregate went 9 percent of the country's total income payments in 1929, 10 percent in 1940, and 12 percent in 1945. The four Southwestern States raised their aggregate share of the Nation's income during the period after 1940 by about 1 percent.

The growth in the relative importance of the Southeast in manufacturing during the 1930's accounts largely for the increasing proportion of income payments going to the South in the years prior to the war. During the period of rearmament and war, the Southern States, with an important share of military establishments and other war activities, showed the tremendous gains indicated.

In dollar amounts of income, the South made more rapid progress than the rest of the country in recovering from the low point of the depression years. By 1940, the Southern States had recovered the 1929 level of income payments, whereas the remainder of the country was still 10 percent below that level. By 1945, southern income was 240 percent of the 1929 amount, compared with 175 percent for the rest of the country. The smallest relative increase among the Southern States was shown by Oklahoma—169 percent of the 1929 amount—the largest by Florida—343 percent of the 1929 amount.

WAGES AND SALARIES AND THEIR COMPOSITION

Aggregate wages and salaries.—The proportion of the country's total wages and salaries which were paid in the South increased steadily from 1929 to 1945—from 14 percent of the total in 1929 to 16 percent in 1940 and 18 percent in 1945 (table 24). The relationship of the South to the rest of the country, with respect to this most important component of income payments, paralleled very closely that of total income payments. The important changes in wages and salaries are reflected in total income.

[1] Source: U. S. Department of Commerce, Survey of Current Business, August 1945 and August 1946.

Aggregate wages and salaries in the South rose from 7,234 million dollars in 1929 to 17,732 million dollars in 1945, an increase of 145 percent. This compares with an increase of only 79 percent for the rest of the country during the same period.

Changes in wages and salaries and their components from the period of rearmament to the end of the war are shown in tables 25 and 26 and chart 2. During this period all the important wage groups in the southern economy, except farm workers, increased their aggregate wage income faster than those in the rest of the country.

Manufacturing wages and salaries.—Manufacturing wages and salaries in the South increased from 1,562 million dollars in 1929, about 10 percent of total manufacturing pay rolls in the country, to 4,653 million dollars in 1945, 12 percent of the country's total (table 25). In general, the prewar gain is attributable to increased factory pay rolls in the Southeastern States. The gain during the war was largely caused by the growth of war manufacturing both in the Southeast and the Southwest.

The South responded to the Nation's need for war materials of all kinds by increasing the relative output of manufacturing in its economy (as measured by wages and salaries) from 23 percent of total pay rolls in 1940 to 28 percent in 1944, the year of greatest war production. While the increase in the Southeast was from 27 percent to 30 percent in 1944, the Southwestern States showed a remarkable change, from 16 to 26 percent. That these changes may not be entirely permanent is suggested by the fact that in 1945 manufacturing pay rolls declined to 29 percent of total wages and salaries in the Southeast and to 22 percent in the Southwest.

The States outside the South gave even greater emphasis to manufacturing during the war, increasing their proportion of manufacturing to total pay rolls from 34 percent in 1940 to 45 percent in 1944. The cessation of war production brought this proportion down to 41 percent in 1945.

Farm wages.—The rise in industrial activity and the decrease in agricultural employment, during the war years, resulted in a decline in the relative importance of farm wages in total wage and salary payments in the South, despite a substantial increase in agricultural wage rates. From 4.4 percent of total wages and salaries in the South in 1929, farm wages declined to 3.9 percent in 1940 and to 3.4 percent in 1945. Agriculture is a less important part of the economy in the rest of the country, and farm wages remained a fairly stable component of total wages—about 2 percent from 1929 to 1945.

Approximately half the country's farm workers are in the Southern States; these workers receive less than 30 percent of total national farm-wage payments. The 319 million dollars paid southern farm

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

workers in 1929 was about a fourth of the farm wages paid in the country in that year. In 1940, southern farm wages were 29 percent of the country's total, and in 1945 the 596 million dollars paid in farm wages was 27 percent of all farm wages. The explanation for the discrepancy between the proportions of total farm workers and total farm wages lies not only in the farm wage differential but also in the large number of unpaid family workers in agriculture in the South.

Federal civilian executive wages and salaries.—Between January 1940 and June 1944, Federal employment of civilians had tripled in the States outside the South; in the South, on the latter date, there were about four times the earlier number. During the war, Government pay rolls for civilian employees became an important component of the total wage bill in the Southern States. In 1940, 5 percent of all wages and salaries in this region were payments to Federal employees in the executive branch. This proportion more than doubled by 1945 and represented 11 percent of total wages and salaries in that year. Government pay rolls of civilian executive employees in the South were 358 million dollars in 1940 compared with 1,439 million in the States outside the South. By 1945, these pay rolls were 1,935 million dollars in the South and 5,349 million in the rest of the country. The increase of 441 percent in the South compares with an increase of 272 percent in the other States.

AGRICULTURAL INCOME

The Southern States, with half the farm population of the country, since the war have received less than a third of the country's agricultural income.[8] In 1929, agricultural income of 2,513 million dollars in these States was 36 percent of the total farm income of the country. By 1945, southern agricultural income was 4,821 million dollars, about 32 percent of the total (table 27).

[1] Includes net income of farm proprietors, farm wages, and rents received by landlords living on farms.
[2] Source: U. S. Department of Commerce, unpublished data.

The greater dependence of this region upon agriculture is indicated by the considerably higher proportion of agricultural income to total income payments than in the rest of the country. Agricultural income was 20.2 percent of total income in the South in 1929, and 15.2 percent by 1940, as compared with 6.3 percent of total income in the remainder of the country in 1929 and 5.6 percent in 1940. In spite of the tremendously increased farm value of the South's principal crops—cotton and tobacco—the proportion did not rise much higher during the war years, being 16.2 percent in 1945 as compared with 8.4 percent in the other States.

---

[8] Includes net income of farm proprietors, farm wages, and rents received by landlords living on farms.

MILITARY PAYMENTS

Military payments[9] during the war were a substantial part of total income payments in the Southern States. The presence in these States of many of the military training installations concentrated large numbers of military personnel and their families in the region. Since military pay is credited to the States in which the personnel are stationed, such payments considerably increased aggregate income in the South.

Military payments in the South rose from 142 million dollars in 1940 to 4,377 million in 1945. The importance of this type of payment is seen in its increasing percentage of total income in the South—from 1.1 percent in 1940 to 14.7 percent in 1945. These proportions were 0.3 percent and 6.8 percent, respectively, for the remainder of the country.

---

[9] Include net pay of the armed forces, family allowance payments, voluntary allotment of pay to individuals, and mustering-out pay.

V.—Regional Wage Differentials[1]

Interest in geographical wage differentials in the United States has centered mainly on North-South deviations. In part, this approach oversimplifies the problem, since it obscures the fact that substantial wage differences also exist within the North as well as within the South.[2] There are many reasons, of course, why the difference between northern and southern wages has been the focus of so much attention. Insofar as wage rates are a determinant of worker income, differences in rates contribute to regional inequalities in standards of living and welfare. In highly competitive industries, such as cotton textiles, the movement of industry to the South and the difficulties faced by trade-unions in maintaining and raising northern textile wages have historically been closely related to regional differences in industry wage levels. Similarly, in other competitive industries, especially those in which a large proportion of the labor force is composed of unskilled and semiskilled workers (as in wooden-nonupholstered furniture, lumber, and cotton garments), the spread between northern and southern wages has been of great economic significance. Moreover, in legislative deliberations on minimum wages it has been apparent that the setting of national levels in various industries is influenced by the level of wages in the lowest wage region.

While the special position of the South's wage level impinges on many problems regarding wage determination in the United States, this analysis does not deal with geographic wage differentials primarily in terms of the North versus the South. Instead, an effort has been made to throw light on significant wage differentials among eight major regions. The data available for this purpose were collected and processed under uniform procedures in 1945 and 1946, and for each of the selected industries nine regional groupings are usually provided—two in the South and seven in the remainder of the country. In view of the fact that the Mountain States contain few large manufacturing industries, comparisons of wages are confined to the following regions: New England, Middle Atlantic, Border States,

---

[1] Prepared by Harry Ober and Carrie Glasser of the Bureau's Wage Analysis Branch. The statistical work for this article was prepared under the direction of Samuel E. Cohen. This section incorporates minor revisions in the material on wage differentials that originally appeared in the October 1946 Monthly Labor Review. It should be noted that all wage figures used in this section are preliminary; necessary changes will appear in the individual Wage Structure reports.

[2] Several studies have shown that the dispersion of wages within the South is considerably greater than within the North. See Carrie Glasser: Wage Differentials, The Case of the Unskilled (New York, Columbia University Press, 1940); and Richard A. Lester: Diversity in North-South Wage Differentials and in Wage Rates within the South (in Southern Economic Journal, January 1946, pp. 238-262).

Southeast, Southwest, Middle West, Great Lakes, and Pacific.[3] It should be observed that these groupings do not imply that wages are uniform within each region. It is believed, however, that the use of eight regions permits a more accurate reflection of regional wage variations than would be obtained from a comparison limited to the North and South.

Characteristic Regional Wage Positions

For the purpose of determining what geographical wage differences are characteristic of the United States today, the data studied consist of straight-time average hourly earnings which exclude overtime payments and other forms of premium income. While these figures are not synonymous with hourly rates, they afford as close an approximation to rates as it is possible to secure with the available wage statistics. Although changes in straight-time hourly earnings owing to wage-rate increases have occurred throughout the country since 1945,[4] it is probable that, on the whole, the adjustments have had less effect on geographical differences than on the absolute level of wages in particular regions. However, to the extent that geographical relationships have been altered, the present findings deviate from the situation as it existed in August 1946.

The main groups of manufacturing and nonmanufacturing industries used in this analysis are shown in table 28. While the choice of industries was limited by the availability of recent information, it was also influenced by the desire to include as many important southern industries as possible, since the relative level of southern wages is a significant part of the present study. However, industries which are found almost entirely in the South, such as cigarette manufacturing, were excluded because meaningful comparisons with other regions were not possible. On the other hand, table 28 does not contain data for such important southern industries as lumber and bituminous-coal mining. For these industries the available wage statistics were not amenable to classification according to the eight broad economic regions. These industries are, however, treated separately in the following discussion. Despite the fact that the sample of industries used in table 28 gives major weight to industries typical of the South,

---

[3] The States included in these regions are as follows: *New England*—Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont; *Middle Atlantic*—New Jersey, New York, and Pennsylvania; *Border States*—Delaware, District of Columbia, Kentucky, Maryland, and West Virginia; *Southeast*—Virginia, Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, and Tennessee; *Southwest*—Arkansas, Louisiana, Oklahoma, and Texas; *Great Lakes*—Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin; *Middle West*—Iowa, Kansas, Missouri, Nebraska, North Dakota, and South Dakota; *Pacific*—California, Nevada, Oregon, and Washington.

Reference is made in footnote 6 to the wage level found in the Mountain States on the basis of such material as is available.

In the Wage Structure reports issued by the Bureau, Virginia was included in the Border States.

[4] The period covered by this analysis is from January 1945 to April 1946, except the railroad industry for which only 1944 data were available.

[1] Excludes premium pay for overtime and night work.

[2] The national average included data for the Mountain region where coverage was obtained.

[3] Source of data: For all industries except telephone, information based on Bureau of Labor Statistics wage survey. Telephone data taken from wage distributions shown in the annual reports of Bell Telephone Companies to the Federal Communications Commission. The regions for this industry are not exactly identical with those for other industries. Virginia was included in the Border States and part of Idaho is contained in the Pacific region. Other minor variations were also necessary because of the nature of the carrier's field of operations.

[4] Insufficient coverage to warrant presentation of regional data. In assignment of ranks, however, the region's position in the industry was based on the small coverage.

and is therefore less representative of the industrial composition of other regions, the coverage in all regions is believed adequate for the purpose of determining the characteristic wage position of each area.

The national average of straight-time hourly earnings of all workers in each industry, shown in table 28, was used as the base (100) to convert the average straight-time hourly earnings for each region into relatives or indexes in order that percentage deviations from the base or national average can be seen easily. Differences in money terms can readily be computed from these figures. For example, the New England index of 99 for all workers in nonferrous foundries is 1 percent below the national average of $1.03 per hour. The actual average rate for New England in this industry was, therefore, $1.02.

With the exception of the Southeast and Pacific regions, table 1 shows that the position of each region in the national wage scale is not uniform from industry to industry. Indeed, it is somewhat difficult to judge, from examination of the table, where some of the regions fall. To assess how consistently a region maintained a certain position, all regions were ranked according to their level of straight-time average hourly earnings in each industry.[5]

The regional wage positions, based on straight-time average hourly earnings of all workers are shown below. Rank 1 represents the highest wage level.

Rank	*Region*	*Number of industries represented*
1	Pacific	29
2	Middle Atlantic	35
3	Great Lakes	33
4	New England	34
5	Middle West	27
6	Border States	32
7	Southwest	30
8	Southeast	35

The Pacific region with great consistency showed the highest wage level, while, with almost equal consistency, the Southeast had the lowest earnings in the country. In 25 out of 29 industries, the Pacific region came out highest; 4 other regions held top rank in a few cases—New England in 2 industries, Middle Atlantic in 4, Great Lakes in 1, and the Middle West in 2 industries each. The indisputably low position of the Southeast is evidenced by the fact that it ranked lowest in 22 out of 35 industries. The Southwest was lowest in 12 industries, New England in 1 (pulp and paper mills), the Middle West in 1 (telephone), and the Border States in 3.

---

[5] The region with the highest average was assigned rank 1, second highest was called 2, and so on, with the lowest region bearing rank 8. Where 2 regions had the same average, the rank was split, e. g., if both were tied for highest place, each received the rank 1.5.

The next step involved the addition of all the ranks of a region; this sum was then divided by the number of industries represented in each region. The result obtained was then used to assign the 8 regions their average position in the national wage scale.

Regional data are not shown in table 28 where industrial coverage was too small or where no coverage was obtained. In some cases, a rank was assigned using the small coverage as a guide. Inequality in the number of industries covered in each region was taken into account by dividing the sum of the ranks of each region by the number of industries represented; the final rank was based on this average.

Only 1 of the 29 Pacific industries had average earnings lower than the national average, whereas in the Southeast only 1 of 35 industries came above the national average, in the Southwest only 1 out of 30, and in the Border States only 7 out of 32 industries (see table 28). New England's industries were almost equally divided (15 below and 18 above the national average) whereas more than two-thirds of the industries in the Middle Atlantic and Great Lakes States had average hourly earnings that exceeded the national average. It may also be noted that, in at least a third of their industries, New England, Great Lakes, Middle West, and the Border States were midway in the national wage scale.[6]

The actual size of the average wage differential between the South and other regions along with the relative importance of each industry in the South, as measured by employment, is shown in table 29, in which data for the Southeast and Southwest were combined. Following are what seem to be the major observations to be drawn from an analysis of these data.

(1) The wage spread between the South and other regions is quite different in various industries. In pulp and paper mills, for example, southern straight-time average hourly earnings in October 1945, exceeded earnings in the Border States and in New England and were exceeded by only 2.5 percent in the Middle Atlantic and Great Lakes States. An indication of an extremely wide differential is found in the women's dress industry where earnings in the Middle Atlantic States were more than double those in the South. In this industry differentiation with respect to product and types of labor utilized is undoubtedly in good part responsible for the great wage disparity. In the Middle Atlantic States, highly stylized and higher priced garments are produced, compared to the South (with approximately 3 percent of the workers) where house dresses and cotton garments predominate.[7] However, even within comparable price lines, a classification which helps to minimize product differences, the wage spread between northern and southern areas is wide.

(2) Pulp and paper mills have been cited as an industry in which southern average hourly earnings were above those in another region.

---

[6] On the basis of a small number of industries, the position of the Mountain States would fall between New England and the Middle West.

[7] While differences in products and character of the labor force make for regional wage variations, there are other important contributing factors such as degree of urbanization, unionization, and method of wage payment. Further study is needed to determine the specific influence of each of these factors on regional wage levels.

To this may be added cigar manufacturing in which the Great Lakes and Border States showed 1.4 percent and 12.3 percent lower wages, respectively. In seamless hosiery, average earnings in the Border States were 11.3 percent less than in the South, while workers in department stores averaged nearly 10 percent less per hour. New England department store workers showed nearly 5 percent lower hourly wages, on the average, than comparable southern workers. It will be observed that in the few industries where the South had a wage advantage, it was mainly with respect to the Border States, a region with the second lowest wage position (when the Southeast and Southwest are merged into one group).

(3) On the basis of the industry data presented in table 29, there appears to be a slight tendency for the wage differential between the South and other regions to be widest in industries which pay comparatively low wages everywhere in the country. Important exceptions include seamless hosiery in which industry-wide straight-time hourly earnings in January 1946 averaged 63 cents as against 62 cents for southern workers. In two relatively high wage industries, electric light and power and fabricated structural steel, the national averages were $1.03 and 97 cents, respectively, compared with averages of 87 cents and 83 cents in the South.

(4) Where the South occupies a dominant position in an industry, the wage differential appears to be considerably less than in many other industries in which only a minor proportion of total employment is in the South. However, important exceptions are evident so that the relationship cannot be said to be consistent throughout. Thus, in cotton-textile yarn mills, wages in New England were 14.3 percent higher than in the South where nearly 92 percent of the workers were employed. In integrated spinning and weaving mills (83 percent of total employment in the South) wages were 2.7 percent lower in the Border States compared with the South and only 8 percent and 5 percent higher in New England and the Middle Atlantic States, respectively. In seamless hosiery the differential varied from 11 percent below the southern average to 16 percent above. On the other hand, in such leading southern industries as furniture (other than upholstered) and cotton garments, southern wages were surpassed by a considerably greater margin. Relatively unimportant southern industries, from the standpoint of employment (such as the metalworking group), showed differentials greatly in excess of those indicated above.

From the preceding analysis the low wage position of the southern regions is clear. This finding can be further supported by an examination of other leading southern industries such as lumber, railroads, bituminous-coal mining, and the building and printing trades.

TABLE 29.—*Straight-Time Average Hourly Earnings[1] of All Workers in Selected Industries in the South, Compared With Other Regions*

Industry and date of survey	South[2]		Percent by which given region exceeds South					
	Percent of total industry employment	Straight-time average hourly earnings	Border States	New England	Middle Atlantic	Great Lakes	Middle West	Pacific
Manufacturing								
Metalworking (January 1945):								
Fabricated structural steel	19.6	$0.83	15.7	25.3	19.3	18.1	4.8	43.4
Ferrous foundries	3.7	.72	20.8	26.4	37.5	44.4	18.1	51.4
Machinery, miscellaneous	4.1	.83	1.2	12.0	16.9	20.5	6.0	37.3

Telephones (October 1945)	20.5	.81	14.8	16.0	25.9	12.3	−3.7	17.3

[1] Excludes premium pay for overtime and night work.
[2] Includes Southeast and Southwest.
[3] Insufficient number of workers to justify presentation of an average.

These industries, for the reason already indicated, were excluded from tables 28 and 29.

The significance of the lumber industry in the South can be gaged from the fact that in 1944 approximately a quarter of a million workers found employment in lumbering operations in that region; this represents over half of total employment in the entire industry. In August 1944, the most recent period for which regional data are available, straight-time average hourly earnings of workers in logging camps, sawmills, veneer mills, plywood mills, and cooperage-stock mills were 13 to 53 percent higher in the North than in the South. In all branches except veneer and cooperage-stock mills, western wages were more than double those in the South (table 30).[8] This wide spread between the South and West is a reflection not only of differences in the general wage levels of the two regions but also of the fact that southern lumbering operations are smaller in scale, are less mechanized, and utilize a higher proportion of unskilled workers.

TABLE 30.—*Straight-Time Average Hourly Earnings of Workers in the Basic Lumber Industry, by Region, August 1944* [1]

Industry branch	West [2]	North [3]	South [4]	Percent South is of North
Basic lumber: Total	$1.18	$0.73	$0.52	71
Logging camps	1.37	.81	.53	66
Sawmills	1.04	.69	.51	74
Veneer mills	------------	.62	.49	79
Plywood mills	1.03	.62	.49	79
Cooperage-stock mills	------------	.59	.52	88

[1] Based on selected occupations. See Bulletin No. 854—Wages in the Basic Lumber Industry.
[2] Includes 3 Pacific Coast States and 8 States in the Rocky Mountain area.
[3] Includes Midwest, Great Lakes, Middle Atlantic, and New England regions.
[4] Includes 9 Southeastern and 4 Southwestern States.

In underground bituminous-coal mines in the fall of 1945, straight-time hourly earnings in northern and southern coal production districts differed very little, contrary to the general pattern in many industries.[9] However, in both of these regions, earnings were on the whole lower than in the West, where less than 10 percent of the tonnage is produced. Table 31, which presents the wage data for this industry, does not show a single rate for each region because of the difficulty of subdividing coal production districts where boundaries crossed regional lines. For this reason the average earnings for each of the districts in the three regions are shown separately. It will be seen that, although the highest southern earnings (District 7) did not exceed the highest earnings in the North or West, several districts within the South had averages which equaled or exceeded those in the North.

In strip mines the spread in earnings between the North and South was noticeably greater than in underground mines. The highest southern strip mining earnings were 12 cents below the highest northern earnings, whereas in underground mines only a 1-cent difference separated the highest district in each of these regions. Strip mining, it may be noted, employs approximately 18,000 workers nationally as against more than 300,000 in underground bituminous mines.

---

[8] For a full report of wages in this industry, see Bureau of Labor Statistics, Bulletin No. 854—Wages in the Basic Lumber Industry, 1944.

[9] A comprehensive (mimeographed) report on wages in this industry is available from the Bureau upon request: Wage Structure of Bituminous-Coal Mines, 1945.

In brief, the pattern of geographical wage differentials in bituminous-coal mining is similar to that observed earlier, to the extent that wages in the West are higher than in the North and South. However, this industry varies from the general pattern, in that differences between northern and southern underground mines are considerably less marked.

Table 31.—*Straight-Time Average Hourly Earnings in Bituminous-Coal Mining, by Coal Production Districts in Three Regions, Fall 1945*[1]

[Number in parentheses identifies Coal Production District]

Branch	North[2]	South[3]	West[4]	Branch	North[2]	South[3]
Underground mines	$1.12 (10)	$1.11 (7)	$1.21 (19)	Strip mines	$1.29 (10)	$1.17 (3)
	1.09 (11)	1.10 (3)	1.18 (20)		1.27 (2)	1.14 (7)
	1.08 (4)	1.07 (8)	1.15 (16)		1.26 (11)	1.12 (15)
	1.07 (2)	1.05 (6)	1.09 (17)		1.21 (4)	1.11 (9)
	1.05 (1)	.95 (14)	------------		1.07 (1)	.96 (13)
	.97 (12)	.91 (9)	------------		.78 (12)	
	------------	.91 (13)	------------			
	------------	.86 (15)	------------			

[1] Average hourly earnings for each district based on a selected number of occupations.

[2] Coal Production Districts within the North include *District 1*—Eastern Pennsylvania, *District 2*—Western Pennsylvania, *District 4*—Ohio, *District 10*—Illinois, *District 11*—Indiana, *District 12*—Iowa.

[3] Southern Districts include *District 3*—Northern West Virginia, *District 6*—Panhandle of West Virginia, *District 7*—Southern West Virginia, *District 8*—Other West Virginia counties and parts of Virginia, Tennessee, and North Carolina, *District 9*—Counties in Kentucky, *District 13*—Alabama, *District 14*—parts of Oklahoma and Arkansas, *District 15*—Kansas and parts of Oklahoma.

[4] Western Districts include *District 16*—Northern Colorado, *District 17*—Southern Colorado, *District 19*—Wyoming and Idaho, *District 20*—Utah. For more exact delineation of district boundaries, see Wage Structure in Bituminous-Coal Mines, 1945.

Wages of southern railroad workers on class I line-haul steam railroads are also lower than elsewhere. Straight-time hourly earnings in 1944 averaged 93.5 cents in the Eastern District, 85.0 cents in the Southern District, and 87.5 cents in the Western District (for the 93 percent of all employees in the industry, on which the Interstate Commerce Commission gives hourly data).[10] It will be observed that unlike most other industries, workers on western railroads had lower hourly earnings than Eastern District workers; in fact the wage spread between the East and West was greater than that between the South and West.

For the building and printing trades regional wage comparisons are based on average union hourly rates of pay, since data are not available currently on wages paid on all types of jobs, both union and nonunion. In table 32 these rates are shown for only two broad geographic regions but with subdivisions within each region by size of city.

---

[10] Based on Railway Statistics for 1944 (preliminary), Interstate Commerce Commission. The Eastern District comprises the Great Lakes, Central Eastern, and New England States; the Western District, the entire area west of the Mississippi, and the Southern District, all States east of the Mississippi and below the Eastern District.

With certain minor exceptions, the basic wage rates paid to train and engine service employees have been uniform throughout the United States since 1944. Among other railway employees, usually called the nonoperating employees, variations in rates do exist from region to region. Generally the differentials are less in the skilled occupations such as shop mechanics than they are in the unskilled jobs such as sectionmen and extra gangmen. In the former the regional differentials between the Eastern and Southern Districts are about 1 cent per hour while in the latter occupations the rates in the Southern District are 8 to 10 cents per hour less than in the Eastern District. The Western District tends to pay better rates to unskilled occupations in the Northwest than in the Southwest.

In all but the smallest cities, union rates in July 1945 were lower in the South than in the North. In the smaller cities (40,000 to 100,000 population) journeymen in the building trades averaged the same in both regions, while in book and job printing, union workers in the South had higher rates than workers in the North in cities of this size.

It will also be observed that the North-South differential for skilled journeymen in the building trades was considerably less than for the less skilled helpers and laborers. In the largest southern cities, journeymen's rates were 9 percent below the North while helpers and laborers' rates were 31 percent lower. The differentials for the least skilled jobs were less in the medium and smallest sized cities but even here they exceeded the wage spread for the skilled job.

TABLE 32.—*Average Union Hourly Rates in the Building and Printing Trades by Population, Group, and Region, July 1945*

Trade	Cities of 250,000–500,000 population			Cities of 100,000–250,000 population			Cities of 40,000–100,000 population		
	North and Pacific (13 cities)	South and Southwest (8 cities)	Percent South is of North	North and Pacific (18 cities)	South and Southwest (7 cities)	Percent South is of North	North and Pacific (7 cities [1])	South and Southwest (6 cities [1])	Percent South is of North
Building trades	$1.49	$1.30	87	$1.38	$1.26	91	$1.31	$1.19	91
Journeymen	1.58	1.44	91	1.48	1.33	90	1.37	1.37	100
Helpers and laborers	1.02	.70	69	.93	.67	72	.89	.77	87
Printing trades	1.22	1.20	98	1.23	1.13	92	1.15	1.19	103
Book and job	1.10	1.08	98	1.14	.96	84	1.02	1.11	109

Variations in Wages at Various Skill Levels

To answer the question whether workers on the same general level of skill receive the same straight-time average hourly earnings in all regions or whether there are characteristic geographical differences, three occupations, believed to be fairly representative of the skilled, medium skilled, and least skilled jobs in each industry, were chosen for analysis.[11] For example, for the telephone industry the jobs selected were PBX installers, experienced switchboard operators, and cable splicers' helpers; for the work-shirt industry, the jobs included sewing-machine repairmen, sewing-machine operators, and work distributors; for full-fashioned hosiery, single-unit knitters, toppers, and janitors. This was done for most of the industries shown in table 28.[12] Some industries could not be covered in this manner because occupational data were not available.

---

[11] The choice of a single occupation to represent all skilled, semiskilled, or unskilled jobs in an industry, of course, limits the validity of the comparison. The margin of error would have been reduced if the selection of occupations had been based on a detailed study of occupational wage relationships in each industry. The Bureau of Labor Statistics (Wage Analysis Branch) has undertaken such studies, a few of which have already appeared in a series of mimeographed reports entitled, "Occupational Wage Relationships." These studies are now available for machinery, machine-tool accessories, foundries, and electric light and power. For purposes of the present analysis, it was necessary to choose occupations prior to a detailed study of each industry. For this reason, the chance of error cannot be entirely dismissed.

Following the procedure used previously, the regions were ranked according to their relative level of straight-time average hourly earnings for each occupation in each industry. The final or average regional wage positions with respect to the three grades of labor are shown below. Rank 1 represents the highest wage level.

	Skilled job	*Semiskilled job*	*Unskilled job*
Pacific	1	1	1
Middle Atlantic	2	2	3
Great Lakes	3	3	2
New England	[1] 4	4	4
Border States	[1] 4	5	5
Southwest	6	[1] 7	7
Middle West	7	6	6
Southeast	8	[1] 7	8

[1] Tied with another region for same position.

The Pacific and Southeast rank highest and lowest, respectively, on this basis, just as they did in terms of the level of wages for all workers in each industry. The Southeast, however, was tied with the Southwest for last position in the case of semiskilled jobs, while New England and the Border States were found to be at the same level with respect to skilled jobs. At the upper end of the wage scale, the Middle Atlantic, Great Lakes, and New England also retained the places shown on the basis of all workers. The major change was for the Middle West; although it is fifth in terms of all workers, it has next to the lowest rates for skilled and semiskilled jobs and third lowest in the case of unskilled jobs. The shift indicated is not too significant since, in the ranking of regions on the basis of the over-all averages, the Middle West preceded the Border States by a very small margin.

The consistency with which the Southeast appeared in a low wage position is evidenced by the fact that in more than half of the industries represented it was lowest in skilled as well as in semiskilled and unskilled jobs.[13]

---

[12] Owing to space limitations, it is not possible to present the detailed tables containing occupational wage rates for the various industries in each region. This material is, however, available upon request.

[13] While in none of the industries covered did skilled workers in the Southeast show the highest wage rates in the country, in a few industries their rates were above those in New England. Thus, production machinists in the machinery industry earned $1.06 per hour in the Southeast in January 1945 compared with $1.02 in New England Adjusters and fixers of seamless hosiery machinery had an hourly rate of 97 cents and 99 cents in New England and the Southeast, respectively.

It is clear from the above that there are characteristic regional wage differences, whether the analysis is made on the basis of all workers or in terms of various skill levels. The Southeast was the lowest wage area from the viewpoint of average wages of skilled and lesser skilled workers and, at the opposite extreme, was the Pacific region, with the highest wages for workers at comparable levels of skill.

WAGE SPREAD BETWEEN SKILLED AND UNSKILLED GRADES

The fact that each region has a characteristic wage position with respect to workers at different skill levels does not necessarily mean that the spread between wages for the highest and lowest grades of work is uniform for all regions even in a single industry. Intra-industry differences are affected not only by the peculiar regional conditions governing the supply of and demand for labor but also by the fact that products manufactured in a single industry are not uniform regionally, the organization of production varies in degree of mechanization and size of operation, and these, in turn, affect the character of the labor force. Within a single industry, also, differences in degree of unionization and methods of wage payment influence not only the general wage level but the relationship of wages among occupations as well.

An analysis of straight-time average hourly earnings of the selected skilled and unskilled job in each of the industries included in this study revealed the following:

(1) Although in all regions the skilled job paid more than the unskilled, the differential in each industry varied from region to region.

(2) On the whole, the wage spread was narrowest in the highest wage region, the Pacific, and widest in the lowest, the Southeast and Southwest.

(3) While the Great Lakes States and New England, two other high wage regions, also showed a narrower skilled-unskilled wage spread than the lowest wage regions, the Middle Atlantic States, second highest in the national wage scale, appeared to have, on the average, as wide a differential as the southern regions but for different reasons.

(4) In the Pacific region the comparatively narrow spread was more the result of the relatively high level of unskilled wages than of the position of skilled wages.

(5) In the Middle Atlantic, the opposite situation seemed to prevail, with earnings of skilled workers (compared to the national average in each industry) considerably higher than those of unskilled workers.

(6) In the Southeast, the wages of both groups varied considerably from the national average for each industry, with a somewhat larger

difference indicated by the wages of unskilled workers. It is interesting to observe the opposite tendencies in cotton textiles and lumber, the two most important industries in this region. In lumber in 1944 the differential against the South among unskilled workers was considerably greater than among skilled jobs. For example, skilled headrig sawyers in the North had only a 16-percent wage advantage over southern workers in this group; among semiskilled edgermen, the northern differential was 37 percent and for unskilled off-bearers the spread was 43 percent. In cotton textiles, according to a Bureau survey made in April-May 1946, the differentials against the South in straight-time average hourly earnings for the least skilled jobs were decidedly smaller than differentials among the skilled jobs. For example, loom fixers, maintenance carpenters, and maintenance electricians earned from 13 to 31 percent more per hour in New England than in the Southeast, whereas among unskilled filling hands, battery hands, and scrubbers and sweepers, the New England advantage did not exceed 8 percent and in some jobs average rates in both regions were identical.

Among the 26 other industries examined in the Southeast, 14 showed that the differential between average hourly earnings in this region and the national average was greater for the unskilled than for the skilled job; for the remaining 12 industries the opposite relationship seemed to prevail. It will be observed from table 33 that all 5 garment industries had a larger differential for skilled workers, whereas in the metalworking industries the spread was greatest for the unskilled. The two branches of the hosiery industry showed different relationships. In the full-fashioned branch the differential was larger for skilled workers, while in seamless hosiery the national average was equaled for the skilled job but fell short by 2 percent in the case of the unskilled job.

In brief, although the difference between skilled and unskilled wages in the Southeast was in general affected to a greater extent by

the low wages of unskilled workers, in a significant number of industries skilled wages showed a greater deviation from the national average than did unskilled wages. It is highly probable that the situation observed in 1945–46 represents a considerable change from the prewar situation because of the fact that wages of the lowest paid workers in many industries during the war tended to rise faster than those of the more highly skilled.

Some Conditions Affecting Southern Wages

The low-wage level of the South is accounted for in large measure by the predominance of agriculture and the relatively large supply of unskilled labor competing for jobs in comparatively few industries. Other important factors include a large population relative to employment opportunities, decentralization of industry, comparative lack of unionization, and limited degree of protective-labor legislation by the States.

Changes in these underlying conditions act to alter the southern wage level. The growth of industry, which received considerable impetus during the war, exerts an upward pull on wages, depending upon the interaction of such factors as the natural rate of population increase in the South, labor displacement in agriculture, migration out of the region, and the rapidity of southern industrial development. The extension of unionization and the raising of the legal minimum wage also contribute toward the establishment of a higher wage level. The prewar 40-cent minimum wage has already been rendered obsolete in many industries by war and postwar wage changes, bringing rates above this minimum.

A strong downward pull on the southern wage level may be exerted as a result of an accelerated growth in the number of workers looking for industrial jobs. This could be effected, for example, by a great displacement of agricultural workers if cotton harvesting and other farm operations were generally more mechanized.[14] If such a revolutionary technological development is not accompanied by a large increase in the industrial and related demand for labor, the pressure on the southern nonagricultural wage level could be considerable. One offsetting factor, of course, would be the extent to which the size of the southern labor force was affected by out-migration.

This brief indication of a few of the many elements that enter into wage determination is sufficient to reveal the complexities of the problem and the difficulties involved in anticipating what the southern wage level—or that of any region—is likely to be in the future in relation to other areas.

---

[14] See Peter F. Drucker: Exit King Cotton (in Harper's Magazine, May 1946, pp. 473–480).

VI.—Wages in Specific Industries in the South[1]

This section contains relatively brief accounts of wages in an important group of southern industries.[2]

The detailed wage surveys on which these analyses are based were made at various times during 1945 and 1946.[3] Hence the data in most cases are not strictly current. Nevertheless, they provide valuable insight into the structure of wages in the South and therefore supplement the discussion of regional wage differentials, which dealt mainly with wage levels.

Cotton Textiles

The manufacture of cotton textiles (woven goods and yarn) is the most important single industry in the South. Although most of the industry is concentrated in an irregular belt extending from southern Virginia through North and South Carolina and Georgia to central Alabama, scattered textile mills are found in all Southern States[4] except Florida.

The South has approximately 50 percent of the total employment in the manufacture of all textile-mill products, including woolens, rayon and other synthetics, and knit fabrics and hosiery, but has a larger proportion in cotton textiles (80 percent) than in the related industries.

Although the manufacture of textile products requires many clearly differentiated operations, it is convenient to make a complete break in the operations at only two points: At the conclusion of the spinning process, at which time the yarn is wound on cones or spools and can be transported easily; or at the conclusion of the weaving or knitting process, at which time the cloth can be transported, if necessary, to a separate plant for dyeing and finishing. Individual mills may, therefore, consist of any of these three general divisions alone or in combination. The typical southern cotton-textile mill is an integrated establishment, combining the spinning and weaving departments. Some of these integrated mills also have finishing departments, and others do a limited amount of simple dyeing. The typical plant produces a relatively standard type of cloth, such as sheetings, twills, drills, duck, or print cloth. In lesser quantities there appear other fabrics, such as ginghams, chambray, napped goods, gauze, or toweling. Although some large establishments produce a variety of goods, most mills have found it advantageous to limit their output to only a few related items. A number of cotton mills are also producing fabrics composed wholly or in part of spun rayon.

---

[1] The analysis of cotton-textile wages in this section was prepared by Alan Ritter of the Bureau's regional office in Atlanta, Ga.; except for coal mining and railroad transportation, the remaining parts of the section were contributed by various members of the Bureau's Wage Analysis Branch.

[2] For each of the industries summarized in the following pages (except railroad transportation), further detail and basic tables with a description of the methods used and information for numerous other industries, is available in a series of wage-structure bulletins. In addition, the Bureau publishes separate tabulations by industry for the more important cities in which each industry is located. Except where otherwise indicated, the Southeast includes Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, and Tennessee; and the Southwest includes Arkansas, Louisiana, Oklahoma, and Texas. Virginia, which was included in the Southeast in the section on regional wage differentials (see p. 1) is not normally included in the data summarized in these notes.

[3] These same surveys provided much of the basic data for the analysis of wage differentials in the preceding section.

[4] For the purposes of this analysis, the Southeast includes Virginia, North Carolina, South Carolina, Georgia, Florida, Tennessee, and Alabama; the Southwest includes Mississippi, Oklahoma, Arkansas, Louisiana, and Texas.

Somewhat smaller in total employment but still important are the region's cotton yarn (spinning) mills. These mills sell yarn to weaving mills or to plants knitting seamless hosiery or underwear fabrics. Some of the yarn mills produce combed yarn, which has gone through an additional preparatory process that removes the shorter fibers, making the yarn stronger and of better appearance. Combed yarns are desirable for knit goods.

Independent weaving mills are not found in large number in the South, being more important in certain Northern States. Such mills usually produce the less common types of cloth, such as plush or upholstery fabrics which may require several varieties of yarn.

There are deviations, of course, from these general classifications. Some integrated mills do not maintain an exact balance between spinning and weaving departments and may sell or buy yarn as a result. The tendency toward the operation of multiple plants under one management has resulted in the increased integration of production under a given company, though separate processes may still be carried on in individual establishments.

For a number of years the Bureau of Labor Statistics has made periodic studies of wage rates and wage practices in the cotton-textile industry. The results of the latest study, based upon an April-May 1946 pay-roll period, form the basis for this summary analysis.[5]

Data are provided in this report for three types of mills—integrated establishments and independent yarn and independent weaving mills. Dyeing and finishing departments connected with integrated establishments are included, but independent dyeing and finishing plants are not included.[6]

---

[5] Earlier reports covering pay-roll periods in 1941, 1943, and 1944 may be obtained from the Bureau of Labor Statistics on request.

[6] A separate study of dyeing and finishing plants was made in July 1946 and copies of the report based upon this study may be obtained from the Bureau of Labor Statistics on request.

The 1946 survey included about one-third of the cotton-textile mills in the South and about the same proportion of the total employment. However, since the various establishments in each of the local areas were not sampled in the same proportion, it was necessary in combining the data for the region as a whole to assign proper weights in proportion to each area's importance in the industry. All of the figures in the tables in this report represent results after such weighting.

AVERAGE HOURLY EARNINGS

Average straight-time earnings of southern cotton-mill workers in April–May 1946 were 74 cents an hour, 27 percent above those for April 1944, and 83 percent above the April 1941 earnings.[7]

The average earnings of all workers were dominated by the integrated mills, where earnings averaged 75 cents an hour. Earnings in southeastern weaving mills were slightly above the general average and those in yarn mills throughout the South were below it, but the number of workers in these two types of mills was not large enough to have an appreciable effect on the general average. Most of the occupations related to the initial preparation and spinning of cotton require less skill and are paid at lower rates than those related to weaving. The varying proportions of higher- and lower-skilled workers among spinning mills, weaving mills, and integrated mills account, therefore, for most of the differences in average earnings. However, workers in the spinning departments of integrated mills frequently earn more than employees in the same jobs in spinning mills.

Average earnings were higher in southeastern mills than in those in the Southwest, owing partly to differences in products manufactured and partly to the fact that recent wage increases had reached fewer southwestern mills. The over-all earnings of men workers exceeded those of women by about 5 cents an hour. Proportionately, more men are employed in the higher-skilled jobs, but, again, men frequently receive more than women workers in the same jobs in all types of mills.

Some operations in cotton-textile mills require relatively little skill and often may be handled satisfactorily by beginners. As a result, large numbers of workers employed in such occupations as scrubbers and sweepers, hand truckers, roving haulers, filling haulers, and battery hands receive rates at or only slightly above the base or minimum rate.

During the past few years, wage adjustments have centered about the minimum rate. The Fair Labor Standards Act, which went into effect in October 1938, originally set 25 cents an hour as the

---

[7] Earnings in Cotton-Goods Manufacture During the War Years, in Monthly Labor Review, October 1944 (p. 823); and Hours and Earnings in Manufacture of Cotton Goods, September 1940 and April 1941, in Monthly Labor Review, December 1941 (p. 1490).

minimum rate for the cotton-textile industry and provided for gradual increases to 40 cents an hour in 1944. However, successive increases recommended by the Textile Industry Committee established under the act, and approved by the Administrator, raised the minimum rate to 32.5 cents an hour in October 1939, to 37.5 cents in June 1941, and to the 40-cent level by April 1942. During the period in which the National War Labor Board was in operation, additional increases in the minimum rate occurred. The rulings of the National War Labor Board affecting the cotton-textile industry took the form of general increases raising the minimum rate to a specified level, with equal or graduated increases in cents to all workers above the minimum. These rulings usually applied directly to only small segments of the industry, but most of the other plants soon adjusted wages in accordance with the rulings. This Board and its successor, the National Wage Stabilization Board, approved increases in the minimum rate to 47.5 cents[8] an hour in August 1942, to 50 cents an hour in February 1944, to 55 cents in February 1945, and to 65 cents in January 1946. Although slightly less than half of the southeastern mills studied reported a 65-cent minimum rate in April–May 1946, this group included most of the larger mills and represented much more than half of the workers.

The distribution of earnings reflects the importance of the minimum rate. In the Southeast only 14 percent of the plant workers received less than 65 cents, but the hourly earnings of almost 50 percent of the workers fell within the 10-cent range from 65 cents to 74.9 cents, and two-fifths of this group were at the 65-cent rate or not more than 2.5 cents above it. A number of southwestern mills reported 55- and 62-cent minimum rates, however, so that about 45 percent of the workers in the Southwest were receiving less than 65 cents an hour in April–May 1946; 17 percent were at the 65-cent rate or slightly above; and only about 30 percent of the workers received rates between 65 and 75 cents an hour. The effects of the lower minimum in the Southwest are also noted in the higher wage brackets. In the Southeast 62.5 percent of the workers received less than 75 cents an hour compared with 77.6 percent in the Southwest; and, similarly, 81.2 percent of the southeastern workers received less than 85 cents an hour, but 91.3 percent of those in the Southwest received less than that amount. An hourly rate of $1 constituted the practical upper limit for both sections, with only 4.3 percent of the southeastern workers and 2.1 percent of the southwestern workers receiving $1 or more.

---

[8] The 47.5-cent minimum was not as generally effective as the others and many southern mills gave increases of more than 2.5 cents in order to attain the 50-cent level of the next increase. See Average Hourly Earnings of Selected Occupations in Cotton Textile Mills, Before and After Wage Increases Granted by the Fourth Regional War Labor Board, February 3 to November 15, 1944, Atlanta Regional Office, Bureau of Labor Statistics, Serial No. IV–22.

A larger proportion of women than men workers were found at or just above the minimum rate. In the Southeast, for example, 16 percent of the women workers received less than 65 cents an hour, and 70.7 percent received less than 75 cents; but 13.2 percent of the men received less than 65 cents and only 57.1 percent received less than 75 cents an hour. To continue up the scale, only 0.9 percent of the women received $1 or more, but 6.6 percent of the men exceeded this rate.

OCCUPATIONAL WAGE STRUCTURE

Average earnings of workers in key occupations in southern cotton-textile mills were obtained in the course of the 1946 wage survey.[9] On the basis of general levels of skill and earnings, these occupations may be grouped as follows:

(1) Higher-skilled maintenance workers, including those with general skills such as electricians, and those with particular skills such as loom fixers. This group, whose occupational earnings averaged more than 90 cents an hour in April–May 1946, is composed exclusively of men workers.

(2) The lower-skilled maintenance workers such as carpenters and card grinders, and the higher-skilled processing workers such as weavers, slasher tenders, and certain dye-house employees, whose occupational average rates ranged between 89 and 80 cents an hour. A large number of women, employed as weavers, appear in this group.

(3) Semiskilled processing workers, illustrated by doffers, spinners, and winders, whose occupational earnings ranged from 79 cents down to 69 to 70 cents.

(4) Relatively unskilled processing workers such as battery hands, custodial workers, and the great number of workers who are engaged in transferring goods in process,[10] whose rates of pay approximated or were slightly above the minimum rate and whose average earnings did not rise above 67 to 68 cents.

As suggested above, southeastern workers generally were paid higher rates than southwestern workers in the same occupations. Men workers also received higher average earnings than women in the same occupations. The average differences were not great, however, and for several occupations in the Southwest women workers received more than men workers.

---

[9] Detailed reports showing occupational earnings for individual areas may be obtained from the Bureau of Labor Statistics on request.

[10] Truckers, filling hands, and roving men.

Regional averages, of course, conceal the usual and significant differences in occupational rates among individual mills, even within the same labor market area.

In addition to differences in the rates paid to individual workers and minor differences among mills in equipment and processes, certain broad factors are generally considered to influence earnings in various mills. The effects of three such factors—method of wage payment, unionization, and size of establishment—may be discussed briefly in terms of selected occupations.[11] Although there are some exceptions, incentive workers, within the occupations compared, received higher average rates than time workers; union plants paid higher rates than nonunion plants; and larger establishments paid higher rates than smaller establishments. Moreover, integrated mills paid higher rates than yarn mills in the occupations for which comparison was made.

Incentive wage plans (predominantly piece rates) appeared in more than three-fourths of the mills visited and affected 36 percent of the total number of workers. Plant-wide incentive plans are rare in the textile industry, but certain occupations are paid almost exclusively on a time basis and other occupations are predominantly incentive.

OCCUPATIONAL WAGE RELATIONSHIPS

In preparing material for table 34, the average earnings for each occupation in each mill were expressed as a percentage of the average earnings of male janitors in the respective mills. Separate computations were made for men and women workers and for time and incentive workers in each occupation. Thus, the pattern of rates in each mill was related to an appropriate base within the mill's own rate structure, and variations in wage levels among mills were eliminated. The average (median) of the relatives for the key occupations studied in the southeastern mills are presented, together with the range within which half of the establishment relatives fell.[12] No attempt was made to adjust these averages to take account of differences in size among the mills, but each establishment was given an equal weight in the positional average. The use of the median also tends to eliminate extreme variations caused by peculiarities in certain mills which would tend to distort the general pattern of occupational relationships.[13]

---

[11] The selected occupations are battery hands, card tenders, ring frame spinners, plain automatic loom weavers, and box loom weavers.

[12] Some occupations which appeared in only a few plants were omitted from this analysis. It was not possible to present a similar tabulation for the Southwest because the small number of plants studied in that region, as well as variations in product, introduced considerable instability into the occupational data.

[13] A detailed discussion of occupational wage relationships will appear in a forthcoming bulletin.

WAGE PRACTICES

Increasing attention has been paid during recent years to certain practices which affect gross income of the workers but which do not appear in the wage scales. At the time of this study 151 of the 222 establishments visited in the South reported paid vacations of 1 week after 1 year of service. Similarly, 101 plants reported insurance or pension plans applicable to plant workers. About nine-tenths of the plans included life insurance and about one-half included some form of health insurance. In addition to the average hourly earnings presented in this report, approximately one-fourth of the plants visited reported the payment of some type of nonproduction bonus, predominantly Christmas bonuses. If the total amount of such nonproduction bonuses was averaged over all plant workers in the industry, approximately 0.3 cent would be added to the average earnings.

[1] Similar information is not available for the Southwest.

RECENT WAGE CHANGES

Subsequent to the April–May 1946 pay-roll period covered in the Bureau's last complete survey of the cotton-textile industry, a large proportion of the textile mills granted wage increases. Most of these adjustments were in the form of a general increase of 8 cents an hour, raising the minimum rate to 73 cents. A large number of these increases became effective in late July or early August. A brief resurvey of the mills included in the original survey was made to determine the increases that had occurred between April–May and August 15 (table 35).

Adjustments of the occupational wage data by the factor presented in this table will not normally result in the same average hourly earnings as would be obtained by a completely new field survey since it does not take into account other factors affecting earnings. Such factors as changes in output of incentive workers, different rates of turn-over, and employment shifts among plants are not included in the general wage changes.

Additional plants have made wage adjustments since August. Average hourly earnings (including overtime) for the United States as a whole for the cotton-textile industry rose from 80.3 cents in July 1946 to 87.5 cents in August, reflecting the general increase of 8 cents. These average earnings rose further to 88.8 cents an hour in September and to 89.2 cents in October 1946. These latter changes indicate that the general increase has been extended to other plants, rather than imply continued increases in plants which had reported raises prior to August 15.

Hosiery

The hosiery industry is composed broadly of two branches—full-fashioned and seamless. A relatively wide differential in wage level exists between these two branches of the industry, reflecting dissimilarities in manufacturing processes, skill requirements of the labor force, location, unionization, and other factors.

Women's full-fashioned hosiery, produced on costly and complicated knitting machines, was made principally from silk before the war. Rayon was the wartime substitute. Since September 1945, nylon has been available in increasing quantities and three-fifths of the full-fashioned mills studied by the Bureau of Labor Statistics in January 1946 reported nylon hosiery as their major product. This proportion probably will increase and, to some extent, affect wage levels.

Seamless (circular knit) hosiery mills use cotton yarns predominantly, and are engaged largely in the manufacture of men's and children's hosiery, although some women's hosiery is also produced.

FULL-FASHIONED HOSIERY

In January 1946, plant workers in full-fashioned hosiery mills in the Southeast averaged 88 cents an hour, exclusive of premium pay for overtime and night work. The corresponding average for workers in the Middle Atlantic States was $1.08; plant workers nationally averaged 97 cents. Approximately a third of the southeastern workers had straight-time average hourly earnings of less than 65 cents as compared with approximately 16 percent in the Middle Atlantic States.

Occupational earnings of men in the Southeast ranged from 56 cents an hour (straight time) for watchmen to $1.58 for one category of knitters. The largest group of knitters numerically (single-unit and backrack [14]) averaged $1.28. Men's earnings in the Middle Atlantic States ranged from a straight-time average of 59 cents for watchmen to $2.06 for a comparatively small group of footers.

---

[14] Backrack knitter operates a legger machine with a backrack attachment that permits knitting the complete stocking in one operation.

Single-unit and backrack knitters in the Middle Atlantic States averaged $1.62.

Among women employees in the Southeast, earnings ranged from 48 cents for inexperienced loopers, toe and heel, to $1.06 for single-unit knitters; the corresponding averages in the Middle Atlantic States were 61 cents and $1.44. In terms of employment, the most important occupations for women were seamers and toppers. Women averaged 73 cents and 70 cents, respectively, in these occupations in the Southeast and 92 cents and 94 cents in the Middle Atlantic States.

Wages were slightly higher, on the whole, in union as compared with nonunion mills. More striking differences were apparent, however, when mills were grouped by size and by size of community; wages tended to vary directly with size of plant and size of community.

The most usual weekly work schedule in January 1946 was 40 hours. Extra-shift operation was reported by a majority of the mills; a differential generally of 5 cents was paid to second-shift workers in about half the mills operating on a multishift basis. Insurance and pension plans were more prevalent in the Southeast than in the Middle Atlantic region, while paid vacations were more common in the latter area.

SEAMLESS HOSIERY

In the seamless branch of the industry, the straight-time average hourly earnings of plant workers in the Southeast were 62 cents in January 1946. This figure compares with 67 cents in the Middle Atlantic States, 57 cents in the Border States,[15] and 63 cents in the Nation as a whole. About 63 percent of the workers in the Southeast received less than 65 cents and hour; the corresponding percentages for the Middle Atlantic and Border States were 52 and 78, respectively. In contrast with the full-fashioned branch, a comparatively small proportion of the workers in seamless hosiery had straight-time earnings of $1 or more.

Women predominate in the seamless industry. Their average earnings by occupation in the Southeast in January 1946 ranged from 44 cents an hour for loopers with less than 1 year of experience and 46 cents for janitors to 65 cents for automatic knitters. Occupational earnings were generally somewhat lower in the Border States and somewhat higher in the Middle Atlantic. For men in the Southeast, earnings by occupation ranged from 53 cents for watchmen to 99 cents for knitting machine adjusters and fixers with more than 4 years of experience.

Union organization was considerably less extensive in seamless than in full-fashioned hosiery, but the wage advantage of union workers was somewhat greater. Earnings for both men and women tended to be highest in the largest mills and in the medium-sized cities.

---

[15] Includes Delaware, Kentucky, Maryland, and West Virginia.

The workweek in seamless hosiery in January 1946 was typically 40 hours. Although a majority of the mills operated more than one shift at this time, shift differential pay was infrequent. Less than half of the seamless mills granted vacations with pay to plant workers or had instituted sickness- or life-insurance benefit plans.

Wood Furniture

Straight-time hourly earnings of plant workers in establishments making wood and upholstered furniture in October 1945 averaged 60 cents in the Southeast region and 64 cents in the Southwest, compared with the national average of 76 cents an hour. In those plants primarily manufacturing wood furniture, hourly earnings of plant workers were 56 and 60 cents in the Southeast and Southwest, respectively, while the earnings of upholstered furniture workers in these regions averaged 73 and 80 cents hourly.

While the earnings of plant workers ranged upward from under 40 cents to more than $1.80 in wood furniture plants, and to more than $2.80 in upholstered furniture plants, the majority of the workers had comparatively low hourly earnings. In wood furniture plants, nearly 80 percent of the workers in the Southeast and over 70 percent of those in the Southwest earned less than 65 cents an hour; in upholstered furniture the corresponding proportions in these regions were over 50 percent and over 33 percent of the plant force. Minimum entrance and job rates in these regions were mainly 40 to 50 cents an hour.

The earnings of men frequently were substantially higher than those of women with comparable work duties. In upholstered furniture, for example, a study of seven jobs in which both men and women were employed in the Southeast in important numbers showed that men's earnings exceeded those of women in the same jobs by 5 to 125 percent.

Hourly earnings of men plant workers in those southern cities in which wood furniture production was most important, Winston-Salem–High Point, Morganton–Lenoir, and Hickory–Statesville, were 60, 66, and 59 cents, respectively; the corresponding averages for upholstered furniture in Winston-Salem–High Point and Hickory–Statesville were 83 and 72 cents an hour. The earnings of women in these areas were significantly below those of men.

In southern wood furniture the higher earnings were generally found in plants with 51 or more employees, but in upholstered furniture small plants reported the higher pay levels. Considering size of community, upholstered furniture plants in areas with 100,000 or more population paid rates about 10 percent higher; in wood furniture manufacture, workers in smaller communities enjoyed an advantage of about 5 percent. No differences in hourly earnings attributable to unionization were found in either region or in either type of furniture manufacture. In the Southeast, incentive workers whose pay varied with individual or group output earned about 9 and 64 percent more, respectively, than time workers in wood and upholstered furniture establishments. In wood furniture the proportions of the labor force paid on an incentive basis were 8 percent in the Southeast and 15 percent in the Southwest; in upholstered furniture in these regions the corresponding proportions were 42 and 36 percent. Most of the plans provided for individual piece rates.

The majority of the Southeast wood furniture plants and Southwest upholstered furniture plants provided for determination of wage rates on an individual basis, the majority in the remaining groups had formal rate structures providing for single rates or a range of rates for each job.

Except for upholstered furniture in the Southeast, the greater number of plants scheduled 44 or more hours per week for first-shift workers. However, very few workers were employed on later shifts and few of these received extra pay for such work. None of the establishments studied reported paid lunch periods for first-shift workers.

Nonproduction bonuses, usually granted at Christmas, were comparatively frequently reported in the Southeast but added only a half cent to the average hourly earnings of plant workers; such bonuses were less common in the Southwest.

Formal provisions for paid vacations, though commonly granted to office workers, were infrequent for plant workers. The most usual provisions offered 1 week's vacation with pay. Only one upholstered furniture plant offered paid sick leave, and only office workers benefited. About a third of the plants in the Southeast had life- or health-insurance provisions, such plans were infrequent in the Southwest. No retirement pension plans were reported.

Tobacco Products

Cigar manufacturing workers in the Southeast, constituting about 40 percent of the Nation's cigar employment, averaged 75 cents per hour in January 1946. The corresponding figure for the country as a whole was 2 cents less. Southern women, who outnumbered men 2 to 1 in the industry, exactly equaled the 69-cent national average for their sex. These favorable comparisons, insofar as the region is concerned, were primarily attributable to the relatively large proportion of workers engaged in making cigars by hand as contrasted to the proportion in other regions where machine methods were predominant. Hand workers require a greater degree of skill than those working on machines and consequently command higher wage scales. Illustrative of the interplay of wages and method of production are the "hand" occupations of bunch making and rolling, which included well over half of the male labor force in the South and whose average earnings of $1.00 and 82 cents, respectively, influenced the southern over-all average for men to a great degree. Nationally, men workers in these two occupations amounted to only about a third of their total in the industry. Because of the large proportion of workers in these occupations in the Southeast, the averages for the country as a whole were the same as those quoted for the region. In most of the other selected occupations studied, the national averages exceeded those of the Southeast. The Southwest region, which had only about 3 percent of the industry's workers, had the lowest regional average in the country—52 cents. Differences in quality of product, combined with a very small proportion of men workers, probably accounted for a great deal of this variation.

Tampa, Fla., is not only the leading southern cigar manufacturing center, insofar as employment is concerned, but also exceeds every other city in the country in this respect. The over-all average earnings for Tampa cigar workers (86 cents) exceeded the regional average for the Southeast by 11 cents and the national average by 13 cents. Tampa women, as a group, bettered the regional and national figures for their sex by 13 cents. Furthermore, on an occupational basis, the averages for Tampa women exceeded the corresponding national averages in most of the cases.

The cigarette industry is concentrated almost exclusively in the States of Virginia, North Carolina, and Kentucky. Plant workers in this industry, numbering somewhat less than 30,000, earned approximately 80 cents an hour on the average, with men averaging about 85 cents and women, slightly more numerous, 75 cents. Two of the main centers of production, Richmond, Va., and Louisville, Ky., had respective over-all average earnings for plant workers of 83 and 74 cents. Richmond men exceeded those in Louisville by only 4 cents but there was a 10-cent difference in the over-all earnings for women.

The third and least important tobacco industry, measured by employment, is the production of chewing and smoking tobacco and snuff. Slightly less than a third of the industry's total estimated employment of about 7,200 workers is located in the Southern States. These southern workers earned about 63 cents an hour, on the average, in January 1946, or about 8 cents an hour less than the national average. Men in the South received 66 cents and women 60 cents.

The respective averages for the country as a whole were 77 and 66 cents. In only 1 of the 12 jobs for which comparisons were made did the earnings of southern men exceed the respective national average. Women's earnings in the South equaled the figure for the country as a whole in but 1 out of 10 jobs.

Workers engaged in the manufacture of tobacco products received specific benefits which supplemented their wages. Four out of every 7 cigar manufacturing establishments, 10 of the 12 cigarette plants, and 6 of the 7 chewing and smoking tobacco plants in the South granted vacations with pay to their employees. One week's vacation was typical in the cigar industry, a two-week's vacation was awarded in all but one cigarette plant, while the chewing and smoking tobacco establishments were equally divided between the two vacation periods. Two-thirds of the cigarette plants had health insurance and/or pension plans. However, only a small proportion of the plants in the other two branches granted this type of benefit to their workers.

Pulp, Paper, and Paperboard Industry

More than one-fifth of the pulp, paper, and paperboard workers in the United States were employed in southeastern and southwestern mills during 1945. The two regions combined produced over 4 million tons of wood pulp and about 4 million tons of paper and paperboard, which represented 42 percent of the pulp and 23 percent of the paper and paperboard produced in the United States for the year.[16] While data for 1946 are not complete, indications are that both production and employment will be substantially higher than for 1945, and it is anticipated that the industry in the South will continue to expand as rapidly as equipment becomes available.

Straight-time hourly earnings for all workers in pulp and paper mills averaged 82 cents in the Southwest and 80 cents in the Southeast region, according to a wage survey conducted by the Bureau in October 1945. These averages were in line with the 82-cent average for the United States as a whole and with those for the Middle Atlantic and Great Lakes regions. Both southern regions exceeded the average of 78 cents in New England and of 73 cents in the Border States, but were surpassed by the Pacific region with $1.03. The proportion of workers in pulp and paper mills earning below 65 cents and $1.00 or above were 37 and 21 percent in the Southeast and 31 and 22 percent in the Southwest, respectively, compared with 15 and 17 percent for the country as a whole. Hourly averages for paperboard mill workers in the Southeast region [17] were 77 cents, with 45 percent of the workers earning less than 65 cents and 17 percent $1.00 or more, compared with 18 and 19 percent earning below and above these amounts for the country as a whole; the national average was 83 cents an hour. Some regional variations not measured by the survey may be attributable to type of paper or paperboard produced.

---

[16] Source: U. S. Bureau of the Census.

[17] The Southwest is omitted because of insufficient paperboard mills to justify presentation of averages, but is included in the averages for the country as a whole.

Earnings of workers in skilled maintenance and in a number of skilled processing occupations tended to be slightly higher for the Southeast and Southwest regions than for the United States as a whole in pulp and paper mills. In the various skilled maintenance occupations, for example, hourly earnings ranged from $1.13 to $1.25 in the Southeast and $1.22 to $1.32 in the Southwest, compared with a range of 99 cents to $1.11 in national averages. Skilled stock preparers averaged $1.17 and $1.16 for the Southeast and Southwest and $1.15 for the United States. Working foremen in processing departments earned $1.15 and $1.22, respectively, in the two southern regions and $1.06 in the country as a whole.

A comparison of earnings in skilled occupations in the two southern regions with those in New England, where earnings were generally considerably lower, clearly reflects the more recent development of the industry in the South with the advantage of modern, wider and higher-speed machines. While these demand greater skill and responsibility of the machine tending and maintenance crews, they also result in higher productivity per worker. Differences in machines are apparent from a comparison of New England paper machine tenders with those of the Southeast and Southwest by machine widths and speeds. In the former region only about one-seventh were tending machines with screens over 150 inches in width and/or operating more than 700 feet per minute, while in the latter two regions combined over two-thirds were tending machines of this type. In all regions, hourly rates of machine crews appeared to be related to machine width and speed in the pulp and paper branch; the same relationship did not exist in the paperboard segment.

Women in the industry in the southern region represented about the same proportion as the 1 out of 8 plant workers reported for the country as a whole. Differences in earnings of men plant workers compared with women workers were somewhat wider than the 29-percent favorable differential for men in pulp and paper mills of the United States, but corresponded closely to the national picture of 22 percent for paperboard mills. As was true for the industry as a whole only a few women were found in skilled occupations and these were confined almost entirely to such work as inspection and paper testing.

Weekly pay of many workers was supplemented by overtime earnings and by shift differential payments. A scheduled workweek of 48 hours for both men and women was reported by about three-fourths of both the pulp and paper mills and the paperboard mills of the two southern regions at the time of the survey. Furthermore, approximately two-thirds of the establishments studied in these two regions paid shift differentials, generally 4 cents to second-shift and 6 cents to third-shift workers in addition to the first-shift hourly rates.

About six-sevenths of the pulp and paper mills and two-thirds of the paperboard mills studied in the two southern regions had union agreements, which were somewhat higher than the national average proportion for pulp and paper mills and about the same as that for paperboard mills. In general, however, unionization was more prevalent in the larger mills, which had a high representation in the southern regions.

Nearly all mills studied in the two southern regions granted paid vacations of 1 week to plant workers and generally 2 weeks to office workers. Almost all plants also had some type of insurance plan for both plant and office workers. Life insurance plans were most common, though some type of health insurance plan was also provided by half the establishments studied in these two regions.

Ferrous and Nonferrous Foundries

Workers in independent foundries comprised one of the largest groups of metalworking employees in the South. In January 1945 these foundry workers numbered about 8,300 and their straight-time hourly earnings averaged 74 cents, compared with $1.01 for the country as a whole.

Average hourly earnings tended to be higher in the Southwest—where three-fifths of these southern foundry workers were employed in January 1945—than in the Southeast. About a third of the ferrous foundry workers and about a fifth of the nonferrous foundry workers earned less than 65 cents in the Southwest, whereas about half of the foundry employees in the Southeast earned less than this amount. The minimum entrance rate for common labor in foundries was most frequently reported as 50 cents in the Southeast and 50 to 60 cents in the Southwest.

Some of the widest variations in average rates among the two regions occurred in molders' earnings. In ferrous foundries, rates of bench molders were $1.05 in the Southwest, about 35 percent higher than the corresponding rates in the Southeast, and the average for floor molders was $1.07 in the former region and 93 cents in the latter. Most of the molders in nonferrous foundries were producing castings by machine; the average for machine molders for the Southwest was about a fifth above that for the Southeast—$1.27 compared with $1.06. Among the lower-paid jobs, the averages for shake-out men in the Southeast were 55 cents in ferrous and 58 cents in nonferrous foundries; comparable averages in the Southwest were 60 and 66 cents, respectively.

In general, workers on nonferrous metals, who accounted for only 1 out of every 8 foundry workers in the South, received higher average hourly rates than employees in establishments casting ferrous metals.

Approximately a third of the ferrous foundries and half of the nonferrous foundries were unionized. Workers in these unionized plants averaged 5 to 10 percent higher than those in nonunionized foundries. Practically all workers in southern foundries were paid on a time basis, although in the country as a whole over a fifth of the workers worked under incentive systems.

At the time of the survey, straight-time hourly earnings of southern foundry workers were appreciably supplemented by premium pay for overtime but not by extra pay for night work. More than three-fifths of the foundries had scheduled workweeks of 48 hours or more. One-third of the ferrous foundries in the Southwest and one-fourth of those in the Southeast operated two or more shifts but less than half of these establishments provided extra pay (typically 5 cents an hour) for this late-shift work. Extra-shift operations were uncommon in nonferrous foundries.

Bonus payments, such as Christmas bonuses, not directly related to the output of individual workers or groups of workers were important in individual plants, but when averaged over all foundry workers in the region, they had little effect on average hourly earnings. In southwestern ferrous foundries, where they were highest, these payments increased the average plant worker's hourly earnings by only a half cent.

Paid vacations for plant workers with a year of service, typically 1 week in length, were provided by one-third of the foundries in the South. Provision for insurance or pensions were fairly common although not as widespread as paid vacation plans; practically all such plans provided for life insurance.

Southern Electric Light and Power Systems

In July 1945, over 60 privately owned light and power systems supplied electric power and transportation, gas, or other allied services to consumers in the Southeast and Southwest. The production and distribution of electricity engaged approximately 24,000 workers in plant and office; about 10,000 more were employed in the subsidiary operations, largely in the Southeast. Southeast systems, although fewer in number, were considerably larger on the average than those in the Southwest and, in total, employed more workers.

A study in July 1945 of electric light and power workers in representative systems showed that men[18] in maintenance, operating, and custodial jobs averaged 87 cents an hour in the Southeast and 89 cents in the Southwest, as compared with an industry average of $1.04. About a fifth of the men in each region earned less than 65 cents an hour, but a greater proportion of Southwest light and power workers earned $1.20 or more (13 percent of the men in the Southwest as against 5 percent in the Southeast).

Occupation by occupation, men generally averaged higher earnings in the Southwest than in the Southeast. For example, journeymen linemen earned $1.09 an hour in the former region as against $1.04 in the latter, district representatives $1.07 and 93 cents, boiler operators 96 and 93 cents. In a few occupations, however, the advantage was in favor of the Southeast.

On the other hand, wage rates of women office workers were higher in the Southeast than in the Southwest. General clerks earned 71 cents an hour in the Southeast and 59 cents in the Southwest; the averages for accounting clerks were 81 and 73 cents, respectively; and those for class A stenographers, 87 and 81 cents.

An examination of system wage scales to determine the prevailing ranking of occupations and the differentials between occupations, percentagewise rather than in terms of cents per hour, showed that the wage pattern of the southern systems differed significantly from that for the industry as a whole. The spread between occupational rates was considerably wider in the South than nationally. The lesser-skilled jobs occupied lower positions, relative to other occupations, in Southern wage scales when compared with the industry-wide pattern; the higher-skilled, on the other hand, held a greater percentage advantage over other occupations in the South than was found nationally. A simplified but representative illustration of these significant features of southern wage scales is afforded by contrasting the spread between selected occupations at distintly different wage levels. Thus, in the South, maintenance electricians, a high-wage group, were paid approximately 23 percent more than substation operators; for the industry as a whole, the advantage amounted to 16 percent. Groundmen, a relatively low-wage group, were paid only 70 percent of the rates for substation operators in southern light and power systems, as against 79 percent nationally. Illustrating another significant aspect of southern wage practices is the fact that office occupations were rated markedly higher, relative to nonoffice jobs, in southern wage scales than in the industry-wide pattern.

The practices of southern light and power systems with regard to related or fringe wage issues can be briefly summarized. Although round-the-clock operation is an industry-wide characteristic, none of the southern systems—and only about a fourth of all systems studied—paid premiums for night work. In about half of the Southern systems studied, the scheduled workweek for first-shift workers was 40 hours; in the rest, more than 40 hours of work was scheduled. Although paid vacations were almost universally offered to light and power plant and office workers, vacation policy of southern systems was more liberal than general industry practice; four out of every five southern systems granted 2-week vacations to their labor force. Formal provisions for paid sick leave were found in almost all the southeastern systems and in less than half of the southwestern systems. Insurance or pension plans paid for in whole or in part by the company were set up in almost all southern systems; nonproduction bonuses, on the other hand, were not common.

---

[18] Few women were employed in nonoffice jobs.

Warehousing and Storage

Plant workers in warehousing and storage establishments in southeastern cities of at least 100,000 population averaged 57 cents an hour on a straight-time basis in July 1945, 30 cents below the national level for the industry but only 3 cents less than plant workers earned in southwestern cities at that time. Miami, Fla., with an average of 78 cents for all plant occupations ranked highest among nine southeastern cities and Charlotte, N. C., the lowest (51 cents). In six southwestern cities, earnings ranged from 56 cents in San Antonio, Tex., to 72 cents in Oklahoma City and Tulsa, Okla.

In each group of cities, 90 percent of the plant workers received less than 75 cents an hour in contrast to 22 percent for the country as a whole. The relatively few higher-paid southern workers included maintenance mechanics, checkers, and working foremen. Handlers and stackers, who accounted for a third of all plant workers in southeastern cities, averaged 53 cents an hour. In the next two numerically important occupations studied by the Bureau, truck drivers' helpers received the same earnings as handlers and stackers, whereas truck drivers earned 60 cents. For comparable work, wage earners in southwestern cities had only a 1- or 2-cent advantage in hourly pay over the southeastern workers.

Undoubtedly, unionization has had a more direct effect on wage levels in the southwestern cities, where 44 percent of the plant workers as compared to 26 percent in the Southeast were employed in union establishments in July 1945. Earnings of union workers in the Southwest either matched nonunion pay levels or bettered them by 1 to 11 cents per hour in 11 key occupations that could be compared. In southeastern cities, however, nonunion workers received higher hourly rates (4 or 7 cents more per hour) in 3 out of 7 comparable jobs.

Because of the heavy nature of work involved in moving and storing goods, men dominate the plant labor force. Their typical workweek exceeded 40 hours; in southeastern cities 35 out of 67 plants had a workweek of 44 to 48 hours, but in southwestern cities 25 out of 53 establishments surveyed scheduled men to work over 52 hours a week.

Paid vacations have become a fairly widespread practice in recent years and in both the southeastern and southwestern cities two-fifths of the establishments had such a policy, offering usually 1 week with pay after 1 year of service. Insurance or pension plans for plant workers were less prevalent in the Southeast, where only 5 plants had such provisions; but 21 out of 53 southwestern establishments had some type of plan, most frequently life insurance. Over two-fifths of the southeastern plants as compared to about one-third of those located in southwestern cities gave their workers a nonproduction bonus, usually at Christmas.

Retail Stores

In April 1945, large southern cities of 100,000 or more population employed some 52,000 (or over 10 percent) of the country's department and men's and women's clothing store employees, and maintained more than 15 percent of all such establishments (with 8 or more workers) in communities of comparable size. The Southeast and Southwest regions combined, including all cities regardless of size, accounted for almost twice this proportion (20 percent) of the limited-price variety store workers, who were employed in almost 30 percent of the country's 5- and 10-cent stores over the minimum size, many of which are affiliated with national chains.

Although none of the characteristic features of these retail establishments is peculiar to the South, interesting variations in wage structure were disclosed within that broad economic area. Unionization, while not extensive in any of these industries throughout the country, was particularly rare in the South. Here, as elsewhere in the Nation, department, clothing, and limited-price variety store workers were predominately women, who, for the most part, were employed in selling jobs that require little or no training or experience. Owing to seasonal factors, part-time work assumes an importance equaled in few other industries.

According to the Bureau's studies, department and clothing store workers (excluding office and executive personnel) in large southern cities earned, on the average, 57 and 61 cents an hour, respectively, in the Southeast and 65 and 70 cents in the Southwest in April 1945. Limited-price variety store employees (in all-sized cities) averaged 33 and 34 cents in the respective regions, with over one-third of the workers receiving less than 30 cents an hour and only 1 percent earning 65 cents or more.

Percentage distribution of department and clothing store workers' earnings disclosed a wide rate range—less than 25 cents an hour to over $2—with proportionately more clothing than department store workers at the high earnings levels. Moreover, 18 to 39 percent of the men in both branches as against 5 to 9 percent of the women earned at least $1 an hour; in department and clothing stores, respectively, men earned over one-third and about one-half more per hour than women.

In general, occupational earnings varied between the two regions in the same manner as over-all earnings did; however, in several important jobs, workers in the Southeast earned more. Notable among these were furniture salesmen who, as the highest-paid men in department stores, averaged $1.65 an hour in the Southeast and $1.34 in the Southwest. Similarly, men selling men's suits, coats, and pants in clothing stores, the most important men's job numerically, as well as the highest-paying, averaged $1.53 in the Southeast and 9 percent less in the Southwest. Women in the two types of stores were most numerous in departments selling women's dresses and coats, averaging from 84 to 90 cents an hour in the South as a whole; a few relatively unimportant selling departments among those studied paid more. Part-time saleswomen in dress and coat departments averaged substantially less than the full-time clerks; in one instance—clothing stores in the Southeast—they earned just half as much. Nationally, the earnings difference in part-time and full-time work was roughly 20 percent in favor of the latter.

Variety store salesgirls, most numerous and perhaps least skilled of all retail clerks studied, averaged 34 and 35 cents for full-time work in the Southeast and Southwest, respectively. Part-time workers, accounting for over half of the total in this job, earned 5 to 6 cents an hour less. Section supervisors averaged the most.

Non-selling workers in the three types of stores were most numerous, in janitorial, stockwork, and cashiering jobs and earned somewhat less than other store workers, including office personnel.

Among 9 large southern cities (100,000 or more population), the level of earnings for department store employees (excluding office and executive personnel) in the highest-wage city was about 20 cents greater than in the lowest-wage city; the range in wage level, by city, in clothing stores was 26 cents and in limited price variety stores 7 cents. Dallas and Houston were, with one exception, the highest paying. The former paid workers in department stores an hourly average of 70 cents; in clothing stores, 68 cents; and in limited-price variety stores, 42 cents. In like order, Houston retail store workers received 65 (Birmingham paid 66), 75, and 42 cents an hour. Tampa and Knoxville were lowest. Among the smaller cities where 5- and 10-cent stores were covered, Miami paid the most—44 cents—and Nashville the least—33 cents an hour

The Bureau's study further revealed that among limited-price variety stores, earnings were higher in the larger communities than in the medium- or small-sized cities, and in the three groups of stores the size of the establishment (as measured by employment) showed a similar relationship to wage levels. Extreme variations in earnings by method of wage payment were apparent in many selling occupations in department and clothing stores, but were less evident in limited-price variety stores where less than 5 percent of the store workers were paid on an incentive basis as compared to over a third in the other two branches. Nationally, incentive workers' earnings in the latter establishments were estimated to be about 35 to 40 percent higher than those of time workers.

The lowest rates paid to qualified workers in each establishment varied little from minimum entrance rates, and in department and clothing stores were concentrated for the most part between 30 and 45 cents an hour; most of the variety stores with established minima had rates falling between 25 and 40 cents. Forty-eight hours per week was the most frequently reported work schedule; however, longer or shorter hours were fairly common. A substantial number of variety stores scheduled men to work 54 hours and over, particularly in the Southwest.

Nonproduction bonuses (generally paid at Christmas) were paid to department store workers in a majority of the establishments studied. The practice was equally widespread among clothing and limited-price variety stores but the bonus tended to be somewhat smaller.

Most of the southern stores provided vacations with pay after 1 year of service; 1 week was most common, with office workers occasionally receiving 2 weeks. Paid sick leave was uncommon among department and clothing stores, but was frequently reported by limited-price variety stores. Two weeks was the most common period allowed in the Southwest variety stores, and 3 weeks in the Southeast.

Of all the establishments, department stores participated most extensively in plans for insurance or pensions for their employees; life insurance was the plan most widely adopted in these as well as in the clothing and variety stores providing such benefits.

Coal Mining

The Southern States produce all types of coal except anthracite and subbituminous. Semianthracite is mined in Virginia and Arkansas; low-volatile bituminous, or semibituminous or smokeless coal, in Virginia, Alabama, Arkansas, and Oklahoma; and high-volatile bituminous, in nearly all of the southern coal-producing States. Lignite, the lowest grade of coal, is produced mainly outside of the Southern States, although the Texas seams are mainly lignite.

The wide distribution of coal resources in the South, combined with the wide range of types of coal, gives to the Southern States a favorable basis for industrial development. The proximity of coking coal in Alabama to abundant iron ores and fluxing materials gives to the Birmingham area an advantage enjoyed by no other region in the country. The down-grade haul of coal to tidewater and cheap coastal transportation facilities vastly broaden the marketing area of southern Appalachian coals. There are exceptional possibilities of by-product industries from the volatile coals of the South.

United States Bureau of Mines figures indicate that the Southern States (excluding West Virginia and Maryland) produced about 18 percent of all coal, including anthracite, in 1944, the proportion rising from about 17 percent in 1939. The States producing more than 1 percent were Kentucky (10.4 percent), Virginia (2.9), Alabama (2.7), and Tennessee (1.1). Output in Texas, which produces lignite, fell from 826,000 tons in 1939 to 109,000 tons in 1944.

The output per man per day, as computed by the United States Bureau of Mines for bituminous-coal for the country as a whole, averaged 5.67 tons in 1944. The average for Kentucky was 5.08 tons; for Oklahoma, 4.92; for Virginia, 4.08; for Tennessee, 4.02; for Arkansas, 3.53; and for Alabama, 3.03. The average for the country as a whole is raised somewhat by the relatively high averages for strip mines and for lignite. There is relatively little strip mining in the South, and southern lignite is limited mainly to Texas. Recent advances in mechanization have placed the South on a basis not radically different from other mining areas. In Kentucky, for example, only 3.2 percent of underground production was mined by hand in 1944, in Virginia 2.6 percent, in Alabama 2.1 percent, and in Tennessee 6.6 percent, as compared with 5 percent in the country as a whole.

Employment in bituminous-coal mining in the South (as defined in this connection) averaged more than 100,000 production workers in 1944. Approximately half of these were in Kentucky; Alabama employed about 22,000; Virginia, about 16,000; Tennessee, about 7,000; and Arkansas and Oklahoma each, between 2,000 and 3,000.

The wages of bituminous-coal miners, as of other groups, have traditionally been lower in the South than in the country as a whole. In 1936, the national average of hourly earnings was $0.733, in contrast to $0.543 in Alabama. The following tabulation shows the averages of leading Southern States in descending order, together with those of West Virginia, Pennsylvania, Utah (which had the highest average), and the national average:

	Average hourly earnings, 1936		*Average hourly earnings, 1936*
Kentucky	$0.719	Alabama	$0.543
Virginia	.679	West Virginia	.801
Oklahoma	.659	Pennsylvania	.799
Arkansas	.635	Utah	.955
Tennessee	.631	United States	.733

Average hourly earnings, even when there is little premium pay for overtime, reflect imperfectly the regional differences in basic occupational rates. The occupational differentials were narrowed from time to time and notably by the wage agreement of 1941. Under that agreement, certain basic day occupations, such as drivers, brakemen, trackmen, and timbermen, received $1.00 per hour in both the Northern and the Southern Appalachian districts of the UMWA and in several other districts. In a few of the western districts the rate was higher; in southern districts outside of the Appalachian territories, as defined for collective bargaining, the rate was lower: in Tennessee, $0.945; in western Kentucky, Arkansas, and Oklahoma, $0.857; in Alabama, $0.821. Rates below $1.00 were also paid in Iowa and Missouri. The removal of the wage differentials between the Northern and Southern Appalachian districts in 1941 applied only to day rates; tonnage differentials remained.

Differences in straight-time hourly earnings of certain occupational groups in the fall of 1945 are shown in table 36. The figures are available only for producing districts as defined by the Bituminous Coal Act of 1937, but they indicate approximately the averages in the South as compared with those of western Pennsylvania, a high-wage Western district (Utah), and the country as a whole.

The averages as given in the table were raised by the increase of 18.5 cents in basic rates made by the 1946 agreement. On a percentage basis, the relatively low southern averages were raised more than the higher averages in other areas.

The averages in the accompanying table include unorganized as well as union mines. The extent of unionization declined in the twenties, especially in the South, but under the National Industrial Recovery Act and the National Labor Relations Act, most of the workers were organized and the unions (primarily the UMWA) obtained collective agreements for substantially all of the workers except in some of the smaller mines. Late in 1941 the union shop was extended to "captive" mines—mines operated by companies, such as steel corporations, which use most of the coal instead of marketing it. Operators of "commercial" mines had earlier accepted the union shop.

TABLE 36.—*Straight-Time Hourly Earnings in Selected Occupations in Bituminous-Coal Mining, Fall 1945*

[Source: U. S. Bureau of Labor Statistics, Wage Structure Series 2, No. 12, Bituminous Coal Mines, 1945, table 6]

Occupation	United States	District number (under Bituminous Coal Act) 2 (Western Pennsylvania)	8 (Eastern Kentucky, southeastern West Virginia, and adjacent areas)[1]	9 (Western Kentucky)	13 (Alabama, Georgia, and southeastern Tennessee)	14 (Arkansas and part of Oklahoma)	20 (Utah)
Underground mines							
Car dumpers, outside	$0.99	$1.03	$1.01	$0.83	$0.82	$0.91	$1.13
Electricians, maintenance:							
Inside	1.21	1.28	1.22	1.04	1.06	----------	----------
Outside	1.17	1.27	1.17	1.01	1.02	----------	----------
Loaders, hand, inside, incentive	1.06	1.04	1.08	.84	1.07	1.00	1.30
Miners, pick, inside, incentive	1.03	1.14	.91	.99	.88	----------	----------
Slate pickers, outside	.95	.98	.96	.83	.80	.91	1.02
Trackmen, inside	1.00	1.00	1.00	.87	.87	.91	----------
Strip mines							
Power-shovel operators	1.64	1.82	----------	1.51	1.38	----------	----------
Slate pickers	.97	.97	----------	.88	----------	----------	----------
Truck and tractor operators	1.03	1.05	----------	.99	.84	----------	----------

[1] District 8 includes southeastern West Virginia but wage rates were substantially uniform throughout the district and for day workers were for the most part the same as in Districts 1 to 7 (the other Appalachian areas). The average earnings, especially of incentive workers, vary with local conditions. The tonnage rates of loaders, for example, are higher in district 2 than in district 8, but straight-time hourly earnings are somewhat higher in district 8 because of conditions which make possible the loading of more coal per hour.

Railroad Transportation

More than 300,000 employees were engaged in the provision of railroad transportation in the 13 southern States in September 1945.[19]

Railway employees are divided into two broad groups, operating and nonoperating. The so-called operating employees include those who actually man and run the trains, such as conductors, engineers, and brakemen. The nonoperating employees embrace all other workers in the railway industry, such as sectionmen, clerks, shopmen, signalmen, and telegraphers. About three out of every four railway workers fall in this nonoperating group.

Prior to 1943 there were slight differentials between the basic daily wage rates paid to operating employees in the East and in the South.[20] The rates in the South were 4 to 7 cents less than those paid in the East; the West usually paid about the same as the South. Through agreements signed during 1943 and 1944 between the carriers and the railway labor organizations, the basic daily wage rates for operating employees were almost completely standardized throughout the United States. As a consequence, the rates in the South today are the same as they are in the East.

---

[19] Monthly Labor Review, May 1946 (p. 754).

[20] As defined by the Interstate Commerce Commission, the Southern District is the area south of the Potomac and Ohio Rivers and east of the Mississippi River. The Eastern District is set off from the Western District by a line drawn from Chicago to St. Louis and then down the Mississippi River to the point where it is joined by the Ohio River.

An illustration of the change which took place during the 1943–44 period may be found in the case of an engineer handling an engine with 200,000 to 250,000 pounds weight on drivers in passenger service. As of April 1, 1943, this engineer received a basic daily wage rate of $8.49 in the East and $8.42 in the South and West. By December 1, 1944, this 7-cent differential had been eliminated and wage rates had been adjusted upward so that the same engineer received the same basic daily wage rate ($8.89) anywhere in the United States. Since that time all operating employees have received an increase of $1.48 in their basic daily wage rates under agreements signed on May 25, 1946. Thus, today the engineer used in the above example would be receiving $10.37 per basic day.

As regards the nonoperating employees, there is far less standardization of wage rates throughout the United States. This group of workers are paid on the basis of hourly rates, while the operating employees are paid on a dual basis of pay (i. e., they earn their basic daily wage whenever they work a certain number of hours or run a certain number of miles, whichever occurs first).

For the most part, there is a tendency for the wage rates paid to the skilled occupations within the non-operating group to be closer to uniformity than is the case in the less-skilled categories. As a consequence, between the South and the East there are greater differentials in wage rates paid the less-skilled workers. For example, the predominant rate in the South and West paid to extra gangmen is 75½ cents per hour, whereas in the East the predominant rate is 83½ cents per hour. The term "predominant rate" means the rate paid to the largest percentage of workers.

Section men also fall in the less-skilled class of nonoperating employees. Their predominant rate in the South and West is 75½ cents per hour, as compared with 85½ cents in the East.

By contrast there is very little variation in the hourly rates paid to shop mechanics, who are members of highly skilled crafts. Shop mechanics include blacksmiths, boilermakers, electricians, machinists, sheetmetal workers, and carmen. The predominant rate for shop mechanics in the South is $1.22½ cents per hour as compared with $1.23½ in the East and the West. Thus, in this skilled group there is only a 1-cent differential but in the less-skilled categories, the differential between the South or West and the East is 8 to 10 cents per hour.

VII.—The Fair Labor Standards Act and the South[1]

The Fair Labor Standards Act of 1938 has as its objective the elimination "in industries engaged in commerce or in the production of goods for commerce, of labor conditions detrimental to the maintenance of the minimum standard of living necessary for health, efficiency, and general well-being of workers . . . without substantially curtailing employment or earning power." Specifically, the act seeks to protect workers engaged in interstate commerce by fixing a minimum level of wages, and establishing a maximum workweek beyond which overtime compensation is required. In addition, provision is made for the elimination of oppressive child-labor conditions.

With adoption of this legislation the Nation endorsed the general principle that there are minimum labor standards to which workers are entitled as a matter of social policy. Today the bitter controversy which preceded the passage of the act is history and there is widespread agreement on the desirability of minimum-wage and maximum-hours requirements. Currently, attention centers on proposals to liberalize the minimum wage provisions of the act and to extend its coverage. That a minimum-wage for workers should be guaranteed by law is no longer seriously questioned.

Because wages in the South at the time of the passage of the act were relatively low, as compared with wages in other geographical regions, southern workers as a group benefited particularly from the wage provisions of the act. At the same time, the economic impact of the act, at the outset, was felt particularly by southern industries.

Information is not available to appraise in precise terms the effect of the act upon workers and industry in the South. Long before the time specified by the act for the implementation of the 40-cent minimum wage, other factors were exercising an upward pull on the general wage level. The effect of defense and war production upon employment and wage levels after the spring of 1941 substantially minimized the economic significance of the legally established minimum. For most covered industries in the South, as elsewhere, minimum rates substantially above the level required by law were voluntarily established. On the basis of available information, however, an effort is made to appraise the significance of the act for the South, following a review of its major provisions.

---

[1] Prepared by Mary N. Hilton of the Bureau's Labor Economics Staff.

The Provisions of the Fair Labor Standards Act

The Fair Labor Standards Act, as approved on June 25, 1938, established minimum-wage and maximum-hours requirements applicable to all employees engaged in interstate commerce or in the production of goods for interstate commerce, with certain specific exemptions. To implement these provisions, the act provided for the creation within the Department of Labor of a Wage and Hour Division which is under the direction of an Administrator appointed by the President, by and with the consent of the Senate.

The act established a legal minimum wage of 40 cents an hour after October 23, 1945, and set up a basic schedule for the gradual achievement of this goal. This schedule required payment of 25 cents an hour from October 24, 1938, to October 23, 1939, and 30 cents an hour from October 24, 1939, to October 23, 1945.

The basic schedule for the implementation of the 40-cent minimum over a period of 7 years represented, in effect, the minimum statutory requirement. With a view to achieving the 40-cent objective as rapidly as was economically feasible, provision was made for the appointment of tripartite industry committees who could recommend for individual industries a minimum higher than that specified in the schedule, but not in excess of 40 cents.[2] The effect of this provision was to make the institution in any industry of a minimum rate in excess of 30 cents during the period from October 1939 to October 1945 contingent upon the recommendation of an industry committee representing labor, industry, and the public. Actually, through the action of industry committees the 40-cent minimum wage for all covered employees in the continental United States was achieved late in July 1944, over a year in advance of the date when it would have become effective automatically under the act.

The hours provisions of the act establish a maximum workweek beyond which payment at time and a half the regular rate is required. The maximum workweek schedule set up by the act provided for a 44-hour workweek from October 24, 1938, to October 23, 1939, a 42-hour workweek from October 24, 1939, to October 23, 1940, and a 40-hour workweek thereafter.

The child labor provisions of the act make it illegal to ship or deliver for shipment in commerce any goods produced in an establishment employing "oppressive child labor." Oppressive child labor is defined as the employment of any person under the age of 16, or between the ages of 16 and 18 in any occupation found and by order declared to be particularly hazardous for the employment of children between such ages or detrimental to their health or well-being. The administration of the child labor provisions of the act rests with the chief of the U. S. Children's Bureau.

---

[2] For a discussion of the working of the industry committees see Minimum Wage Fixing Under the United States Fair Labor Standards Act, by Harry Weiss, *in* International Labour Review, January 1945.

The Importance of the Wage and Hour Provisions to Southern Workers

The economic situation has undergone marked changes since the Fair Labor Standards Act was enacted over 8 years ago. The wage provisions of the act do not have the same economic significance today that they had in 1938. During the war years the hours provisions took on a new meaning. Consequently, the act needs to be viewed in historical perspective.

At the time the act was passed a substantial proportion of the Nation's labor force was unemployed and the earnings of many who were employed stood at low levels. Viewed against this background the broad social objectives of the Fair Labor Standards Act at the time of its passage are clear. Its most important purpose was to assure workers engaged in interstate commerce a reasonable minimum level of wages and to protect workers from excessively long hours of labor. At the same time, it sought through the minimum wage provisions to increase purchasing power and through the overtime pay requirement to create additional employment opportunities.

The minimum wage provisions had immediate importance in terms of higher wage rates for many workers. In view of the fact that a substantially greater proportion of southern workers were earning less than the minimum wage than were workers in any other part of the Nation, the act had particular significance for southern workers in terms of the immediate wage increases which it required.

The only available estimate regarding the total number of workers whose wages were immediately affected by the act relates to April 1939 and the probable impact of the 30-cent minimum.[3] This information indicates that a total of 411,200 workers, or 18 percent of all southern workers covered by the act, were receiving less than 30 cents in the spring of 1939 (6 months prior to the effective date for the establishment of the 30-cent statutory minimum) as compared with approximately 3 percent for the remainder of the country. The 13 Southern States accounted for over 50 percent of all covered workers receiving less than 30 cents per hour as of that date.

Data affording some indication of the immediate significance of the 25- and 30-cent minima to unskilled workers in the South and

[3] Bureau of Labor Statistics: Estimated Number of Workers in April 1939, Subject to Provisions of the Fair Labor Standards Act Effective October 24, 1939. (Mimeographed report.) Washington, 1939.

TABLE 37.—*Distribution of Workers Receiving Less Than 30 Cents an Hour, All Industries, April 1939*

[Source: Department of Labor, Report of the Administrator of the Wage and Hour Division for 1939]

Region or State	Estimated number of workers subject to FLSA	Workers receiving less than 30 cents an hour	
		Estimated number	Percent of covered employees
Total, all States	[1] 12,652,700	[2] 690,000	5.5
All States except Southern States	10,367,300	278,800	2.7
Total, Southern States	2,285,400	411,200	18.0
Alabama	173,300	38,200	22.0
Arkansas	66,600	17,100	25.7
Florida	102,700	23,800	23.2
Georgia	215,000	57,000	26.5
Kentucky	181,500	13,500	7.4
Louisiana	136,500	22,600	16.6
Mississippi	71,400	26,000	36.4
North Carolina	322,200	60,600	18.8
Oklahoma	104,600	5,700	5.4
South Carolina	156,200	41,400	26.5
Tennessee	212,000	43,200	20.4
Texas	330,000	35,500	10.8
Virginia	213,400	26,600	12.5

[1] The United States total includes 41,000 covered employees of mail-order houses. These employees are not included in the State figures. The United States total also includes a roughly estimated total of 11,000 covered employees in the Territories of Alaska and Hawaii.

[2] Does not include homeworkers, longshoremen, and employees of mail-order houses.

Southwest[4] are also available. This information, which relates to average hourly entrance rates for adult male common laborers in July 1938 and July 1939, shows that in July 1938 the average hourly entrance rate for 13 percent of the adult male common laborers in the South and Southwest was under 25 cents as compared to less than a tenth of 1 percent for the North and West.

By July 1939, following the establishment of the 25-cent minimum, the percentage below 25 cents for the South and Southwest amounted to less than a half of 1 percent while 34.6 percent were receiving less than 30 cents an hour.[5]

The information summarized above provides an indication of the importance, in terms of the number of workers affected, of the 25-cent minimum wage of 1938 and the 30-cent minimum of 1939 to wage earners in the South. Comparable information is not available regarding the number of workers who received direct pay increases as a result of wage orders establishing minimum wages above 30 cents an hour. The 40-cent minimum was reached at varying times in different industries and in some instances involved a succession of intermediate steps. In the case of cotton textiles, for example, three steps were required. For the Nation as a whole, an estimated 1,600,000 workers received direct pay increases as a result of 40-cent wage orders, while the total number of all wage increases resulting directly from the issuance of wage orders is estimated at nearly 2,700,000.[6] In addition, many other workers who were earning more than the established minimum received indirect pay increases as a result of the wage orders.

---

[4] The South and Southwest region includes the following States: Alabama, Arizona, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia.

[5] Entrance Rates of Common Laborers in July 1939, in Monthly Labor Review, December 1939.

Today the 40-cent legal minimum applies to all workers covered by the minimum wage provisions of the act, except, in some industries, to workers classified as learners, apprentices, or handicapped. Indeed, as has been pointed out, this goal was achieved more than a year in advance of the October 24, 1945, deadline set by the act. In marked contrast with the early years of the act, the legal minimum is presently of relatively minor significance as a positive factor in the determination of wage rates. For most industries and areas, prevailing minimum rates are well above the 40-cent hourly rate required by law.

In this connection if is of interest to consider the experience of the National War Labor Board, the agency which administered the wage stabilization program during the war years. One of the few grounds on which the Board could approve or order wage increases was the elimination of substandards of living. The Board at the outset approached the question of the rate that could be approved on the substandard criterion on a case by case basis. As experience accumulated, however, the Board found it desirable to establish a definite substandard rate up to which increases could be made without Board approval. The details of the development of this policy will not be traced here. The significant fact to be noted is that during the period from 1943 through 1945 the Board gradually raised its substandard minimum from 40 cents per hour to 55 cents per hour. Subsequently, the National Wage Stabilization Board [7] early in 1946 increased the substandard minimum to 65 cents.

The substandard minima established by the War Labor Board must be carefully distinguished from the minimum wage provisions of the Fair Labor Standards Act. The payment of the 40-cent minimum set forth in the act is now compulsory for the employees covered; the substandard minima established by the War Labor Board were permissive. Employers could raise wages up to the substandard level but were not required to do so. In dispute cases involving substandards of living, the Board proceeded largely on a case-by-case basis in determining the appropriate minimum rate.

---

[6] U. S. Department of Labor, Wage and Hour and Public Contracts Divisions, Annual Report for the Fiscal Year Ended June 30, 1944.

[7] Successor agency to the National War Labor Board.

The practical result of the War Labor Board's substandard policy was a widespread upward movement in prevailing minimum rates in industries and areas where existing rates were below the substandard minimum established by the Board. In the Board's southern region,[8] in particular, the substandard criteria provided an important basis for wage increases. In many plants the common labor rate was raised from the neighborhood of 40 cents an hour to 55 cents or more under the stabilization program.

The history of the substandard policy of the War Labor Board contributes to an understanding of the waning significance of the legal minimum during the period when stabilization of wages was the established Government policy. The increases permitted under the Board's substandard policy, together with post VJ-day wage-rate advances, have greatly reduced the importance of the legal minimum as an economic factor influencing the minimum wage level.

As indicated earlier, Congress in enacting the Fair Labor Standards Act sought to protect workers from wage rates so low that they would not provide a reasonable minimum standard of living. The 40-cent minimum which would provide an annual wage of $832 at full time—40 hours a week for 52 weeks—was considered the best approximation to this goal that was practicable in the light of economic conditions in 1938. Even if this amount were considered adequate to meet the minimum cost of living at prices which existed at that time, it is clear that the statutory minimum does not at the present time serve to protect workers from substandards of living. The rise in the cost of living alone as measured by the Bureau's consumers' price index would require a minimum of approximately 60 cents as of November 1946 as the equivalent of the 1938 objective.

As early as 1944 the Administrator of the Wage and Hour and Public Contracts Divisions of the United States Department of Labor recommended "that the Congress consider raising the limit of the wage which the industry committee may recommend to some higher figure than 40 cents."[9] When Congress in 1945 had under consideration a bill to amend the Fair Labor Standards Act to permit an immediate upward revision of the statutory minimum to 65 cents, with an ultimate adjustment to 75 cents, the Department of Labor favored the adoption of these provisions.

Economic Effect of the Wage Provisions on Southern Industries

In the foregoing section attention was focused upon the importance of the Fair Labor Standards Act to southern workers in terms of the number who benefited as a result of the establishment of a legal minimum wage. A question of equal importance concerns the economic consequences of the wage provisions of the act to southern industries.

---

[8] The region included the following States: Alabama, Florida, Georgia, North Carolina, Mississippi, South Carolina, Tennessee, and Virginia.

[9] U. S. Department of Labor, Wage and Hour and Public Contracts Divisions, Annual Report for the Fiscal Year Ended June 30, 1944 (p. 9.).

The establishment of a legal minimum wage represents both a social and an economic judgment concerning the lowest wage for which labor should be hired. An economically sound minimum wage level benefits not only employees but industry and the economy as a whole. Experience reveals that a properly established minimum wage tends to increase the productive capacity of workers as a result of the improvements in physical well-being and morale that higher wages make possible. Moreover, the imposition of a legal minimum wage may serve to stimulate improvements in managerial efficiency and to give impetus to the introduction of technological improvements that serve to enhance labor output. Substantial increases in productivity thus may result from lifting the wages of the workers at the low end of the wage scale. From the standpoint of the economy as a whole, the establishment of a minimum wage level is also beneficial to the extent that aggregate purchasing power in the hands of employees is increased.

An indication of the economic impact of the Fair Labor Standards Act on wages and employment in the South for the period 1938–41—that is, for the period prior to the great changes in wage and employment levels caused by the demands of the defense program and of the war—is provided by studies which have been made of particular industries.

Early wage orders under the Fair Labor Standards Act established a minimum rate of 32½ cents an hour for a number of relatively low-wage industries, including seamless hosiery, cotton textiles, and men's cotton garments.[10] Table 38 is designed to throw light on what happened to the general level of wages and the wage structures of these industries in the South following the effective date of these orders.

The earnings data presented in table 38 for each of the two periods shown relate to identical plants in the seamless hosiery and men's cotton garment industries, and the data for the two periods in the cotton goods industry are generally comparable. For both cotton textiles and seamless hosiery, wage studies were made by the Bureau of Labor Statistics just prior to the effective date of the Fair Labor Standards Act, and again in the fall of 1940, approximately a year after the 32½-cent wage orders had been issued.[11] For men's cotton garments, detailed wage data are available for the spring of 1939, when

---

[10] The term "men's cotton garment industries" as used in this discussion includes two industry groups: dress and sport shirts, collars and nightwear; and cotton pants, overalls, and work shirts.

[11] See Monthly Labor Review, June 1941, Earnings in Seamless-Hosiery Industry Under 32.5-Cent Minimum Wage; and December 1941, Hours and Earnings in Manufacture of Cotton Goods, September 1940 and April 1941.

Table 38.—*Percentage Distribution of Workers in Specified Industries in the South, by Average Hourly Earnings for Selected Periods*

[Source: U. S. Bureau of Labor Statistics]

Average hourly earnings	Seamless hosiery		Cotton goods		Men's cotton garments	
	September 1938	September 1940	August 1938	September 1940	Spring 1939	Spring 1941
Under 32.5 cents	57.4	3.9	44.2	1.3	73.6	2.9
32.5 and under 35.0 cents	8.4	35.7	14.5	47.4	6.0	48.8
35.0 and under 37.5 cents	7.4	14.3	10.3	12.6	5.2	8.5
37.5 and under 40.0 cents	5.5	10.6	7.1	9.1	5.2	20.9
40.0 and under 42.5 cents	4.9	8.5	5.7	6.9	2.5	4.8
42.5 and under 47.5 cents	6.0	11.1	8.4	9.7	3.5	6.6
47.5 and under 52.5 cents	3.5	6.5	5.5	6.6	1.8	2.9
52.5 and under 57.5 cents	2.0	3.4	2.6	3.6	.8	1.3

Average hourly earnings	$0.331	$0.402	$0.348	$0.385	$0.307	$0.372

[1] Less than a tenth of 1 percent.

the 25-cent statutory rate was in effect, and for the spring of 1941, about 9 months after 32½-cent wage orders were made effective in these industries.[12]

It is clear that the establishment of the 32½-cent minimum exercised a decisive influence on the wage structures of these industries. Immediately prior to the effective date of the Fair Labor Standards Act considerably over half (57.4 percent) of the seamless hosiery workers in the South and over two-fifths (44.2 percent) of the cotton goods workers were earning less than 32½ cents an hour. In the spring of 1939 with the 25-cent statutory rate in effect, almost three-fourths (73.6 percent) of the men's cotton garment employees had averaged hourly earnings of less than 32½ cents.

The effect of the wage orders was to compress the lower segments of the old wage structures, with the result that customary differentials in the lower wage brackets often were not maintained. Thus, in the seamless-hosiery industry in September 1940 over a third of the workers were earning between 32½ and 35 cents an hour, while almost half of the cotton-goods workers were found in the same interval. Similarly, in the men's cotton garment industries about half of the workers were in this wage bracket in the spring of 1941. Small proportions of the workers in each industry were earning less than 32½ cents an hour. Most of these workers were employed at subminimum rates under the terms of learner or handicapped worker certificates.

---

[12] See Monthly Labor Review, August 1942, Earnings in the Men's Cotton-Garment Industries, 1939 and 1941.

At the same time the wage adjustments which occurred were more extensive than can be accounted for solely by the raising of the lowest paid workers to 32½ cents. For example, in each of the industries the proportion of workers earning 40 cents an hour or more increased appreciably after the introduction of the 32½-cent minimum. In seamless hosiery, the proportion of workers earning 40 cents an hour or more increased from 21.3 percent in September 1938 to 35.5 percent after the introduction of the 32½-cent minimum.

By September 1940, average hourly earnings in the seamless hosiery industry had increased by 21 percent and in cotton goods by 11 percent over the levels prevailing just prior to the effective date of the act. By the spring of 1941, wages in the men's cotton-garment industries were 21 percent above the average for the spring of 1939 when the 25-cent minimum was in effect. The extent of this latter increase is partially accounted for by the fact that over the 2-year period the volume of public contracts, for which a 37½-cent or 40-cent minimum wage was fixed, increased substantially.

Some information is also available on the employment experience in these industries in the South, following the establishment of the 32½-cent minimum, and is summarized in table 39.

TABLE 39.—*Changes in Employment in Identical Plants in Specified Industries in the South for Selected Periods*

[Source: U. S. Bureau of Labor Statistics]

Industry	Number of workers		Changes in employment	
			Number	Percent
	1938	1940	1938 to 1940	
Seamless hosiery	13,431	12,689	−742	−5.52
	1939	1941	1939 to 1941	
Men's cotton garments	8,597	9,741	+1,144	+13.3
Dress and sport shirts, collars, and neckwear	2,901	2,890	−11	−.4
Cotton pants, overalls, and work shirts	5,696	6,851	+1,155	+20.3

Employment in 61 identical seamless-hosiery establishments in the South surveyed in both 1938 and 1940 fell from 13,431 to 12,689. Analysis of changes in employment by plant wage groups indicates that it was among the low-wage plants (those with plant average hourly earnings of less than 32½ cents prior to the effective date of the Fair Labor Standards Act) that worker displacement occurred. Such plants were apparently forced to make the most drastic changes in machinery and methods in adjusting to the legal minimum. On the other hand, those plants in the South with plant average hourly earnings of more than 32½ cents in 1938 employed 1.1 percent more workers in 1940.[13]

In the men's cotton garment industries, employment in 14 identical plants in the dress-shirt industry in the South remained practically unchanged between the spring of 1939 and the spring of 1941. In the work-clothing industry, employment in the South increased by 20 percent during the same period. In both of these industries, the stimulus of the defense program was being widely felt by the spring of 1941.

A study of separations of subminimum workers in the cotton-garment industry in the South between March 1939 and March 1941 indicates that for the 2-year period 29.7 percent of the workers earning less than 30 cents an hour in the spring of 1939 were separated as compared to 26.4 percent of the workers earning over 30 cents. The conclusion is that "the earnings of the workers exercised a constant though moderate influence on separations."[14]

In the cotton-goods industry no data on employment changes in identical establishments have been tabulated for this period.

In general, the available evidence regarding the impact of the 32½-cent minimum on wages and employment in the seamless-hosiery, the cotton-goods, and the men's cotton-garment industries in the South indicates that wage adjustments somewhat more extensive than those required to raise subminimum wages to the minimum were made without any substantial adverse effect on employment.

There were, of course, other types of adjustments concerning which little information is obtainable. Undoubtedly the establishment of minimum wage standards resulted, in many firms, in managerial effort to increase labor efficiency and in the introduction of technological improvements.

Effect of the Hours Provisions on Southern Industries

The hours provisions of the Fair Labor Standards Act, by requiring the payment of time and a half for covered employees for weekly hours in excess of 44 during the first year of the act, 42 during the second year, and 40 hours thereafter, were designed to discourage the existence of a longer workweek. The act reflected the generally accepted view that a maximum workweek of not more than 40 hours was socially desirable, and that its widespread adoption would tend to increase employment.

[13] U. S. Department of Labor, Wage and Hour Division, Minimum Wages in the Seamless-Hosiery Industry (mimeographed, April 1941).

[14] Effects of a Minimum Wage in Cotton-Garment Industry 1939–41, in Monthly Labor Review, February 1942 (p. 327). Reprinted as Serial No. R. 1415.

Available information regarding the impact of the hours provisions upon southern industry is very limited. As of April 1939, 6 months prior to the effective date for the 42-hour workweek, it was estimated that of the 2,285,400 southern workers subject to the provisions of the Fair Labor Standards Act, 560,100 or 24.5 percent were working more than 42 hours per week. Of those persons who were working more than 42 hours, 420,400 workers or 75.1 percent were receiving less than time and a half for hours worked in excess of 42.

[1] Includes 41,000 covered employees in mail-order houses, not included in State figures, and a roughly estimated total of 11,000 covered employees in the Territories of Alaska and Hawaii.

[2] Does not include homeworkers, longshoremen, or covered employees in the Territories.

[3] Does not include homeworkers, longshoremen, and covered employees in mail-order houses and in the Territories.

It will be noted from table 40 that the impact of the overtime requirement in relation to the 42-hour week was not markedly greater in the South than in all other States combined.

With the coming of the war and the urgent necessity for the production of war goods, the overtime provisions of the act ceased to serve their peacetime purpose of discouraging work beyond 40 hours a week and operated instead to enable war industries, in which production needs required the establishment of a longer scheduled workweek, to attract the needed manpower without making undue increases in basic rates. On this point the Wage and Hour Division has pointed out:

> The constructive part played by the Fair Labor Standards Act itself in the shift over to war production has not been generally understood. In the first place, as has been said, in the 4 years that the act has been in force, it led to the use of new workers, providing a larger number of skilled hands than would otherwise have been available when our war need for industrial expansion came upon us. Industry committees under the act, bringing together employers, labor, and the public with equal representation, charged with setting the highest minimum wage up to 40 cents that would not substantially decrease employment, have over the years helped to develop in leadership and mutual confidence many of those who now have emerged to guide the national industrial effort. But the greatest contribution has been made by the overtime provisions of the act in attracting labor in a democratic way, without compulsion, to the war industries where it was needed. [15]

ENFORCEMENT

Between October 1938 and June 1946, over $18,000,000 in restitution of wages illegally withheld under the Fair Labor Standards Act had been agreed to or ordered paid to over 570,000 workers in 28,070 establishments in the 13 Southern States. Over half of these cases involved failure to pay the appropriate minimum wage.

Column 1 of table 41 summarizes the combined results of inspections under the Fair Labor Standards Act from its enactment in 1938 and under the Public Contracts Act[16] during the period from October 1942, when the Wage and Hour and Public Contracts Divisions were consolidated to June 1946. Comparable information broken down for three separate time periods is shown in columns 2, 3, and 4. It should be noted that the information presented does not relate exclusively to the enforcement of the Fair Labor Standards Act although that act, in view of its much broader coverage, accounts for the bulk of the enforcement work.

During the period since the enactment of the Fair Labor Standards Act the percentage of inspected establishments found to be in violation of the minimum wage and/or overtime provisions was 45 percent for the Southern States as compared with 49 percent for all other States combined. For the most recent period for which information is available, July 1945 to June 1946, the comparable percentages were 51 for the Southern States and 47 for all other States combined. It is to be noted that violations of the minimum wage provisions are

---

[15] U. S. Department of Labor, Wage and Hour and Public Contracts Division, Annual Report for the fiscal year ended June 30, 1942, (pp. 3–4).

[16] The Public Contracts Act applies to all contracts made by the Government for the manufacture or the furnishing of materials, etc., in the amount of more than $10,000. Certain prescribed labor standards must be maintained by the contractor, including a basic 8-hour day and 40-hour week (overtime is permitted provided time and a half the workers' regular rate is paid for daily or weekly overtime, whichever results in the greater compensation), and the maintenance of the prevailing minimum rate of wages in the locality where the work is to be performed where such a minimum wage determination has been issued by the Secretary of labor.

[1] The statistics include information on 35,000 establishments inspected under the Public Contracts Act since the consolidation of the Wage and Hour and Public Contracts Divisions. Most of these were inspected concurrently under both acts. The figures on violations and restitution represent the compliance record of these establishments under either or both acts.

[2] Since some of the establishments were inspected more than once, the 336,119 establishments inspected represent a somewhat smaller number of *separate* establishments.

[3] Excludes establishments out of business or with no covered employees. Some of the inspected establishments are not represented in the estimates of total coverage, since many have gone out of business since inspection.

[4] Not available.

more widespread in the Southern States than elsewhere. Thus, for the year ending July 1946, 17 percent of the establishments inspected in the Southern States were found to be in violation of the minimum wage provisions as compared with 9 percent for all other States combined.

Of the establishments found to be in violation of the minimum wage and/or hours provisions of the act during the period October 1938 to June 1946, 69 percent of the establishment in the Southern States agreed (or were ordered by the court in a few cases) to pay restitution compared with 84 percent in other States. Comparable figures for the year ending June 1946 show that 77 percent of the southern establishments and 82 percent of the establishments in other States found to be in monetary violation agreed or were ordered to pay restitution. Thus, over the whole period there has been a marked increase in the proportion of southern firms in monetary violation that have agreed to restitution. This is important, since many employees cannot risk or afford to bring suit against their employers for back wages in accordance with their rights under the Act.[17]

In considering the information presented in table 41 it should be emphasized that there is no reason to believe that the compliance conditions found upon inspection are representative of compliance conditions generally, or that the inspected establishments are equally representative of all establishments in a particular area. It should be noted, in particular, that many inspections are made on specific complaint and hence the proportion of violations to total inspections does not accurately reflect compliance conditions in an industry or area.

---

[17] The Administrator of the Wage and Hour and Public Contracts Divisions recommended to Congress in his Annual Report for the fiscal year ended June 1946 that he be granted the power to bring suit on behalf of underpaid employees.

VIII.—Living Costs in Large Cities in the South[1]

From the outbreak of war in Europe until June 1946, retail prices of goods and services used by moderate-income families rose more rapidly in most large cities in the South[2] than the national average for large cities in the United States. Increased industrial activity and concentrations of military establishments in the South during the war gave rise to sharp advances in consumers' prices in southern cities, large and small. Living costs are still somewhat lower in southern cities, however, than costs in a number of northern cities, but the differences are not as great as they were before the war.

Long before the United States entered World War II, the South was beginning to assume a new role in the American economy. It became evident after the beginning of the war that the South was to become an important training center for the armies of the United States and to contribute mightily to the rearming of the Nation. As large military installations were established and production facilities were multiplied many times over, families of soldiers and war workers flocked into many southern cities. Population increases were tremendous. Between 1940 and 1944, 313,000 additional residents settled in the Hampton Roads area in Virginia, an increase of 91 percent over 1940; Mobile's population increased by 68 percent; and Charleston's, 57 percent. Communities that had but small excess capacity to accommodate additional population found their normal population increase of 10 years appearing overnight. Housing shortages immediately became severe, vacancies disappeared, and the pressures for higher rentals and prices of scarce goods accumulated week by week. New residents had to have housing and household goods, food, clothing, hospital care, dental services, and many other living essentials. As areas became more congested[3] the prices of living essentials rose sharply in both large and small southern cities.

Between August 1939 and June 1946, consumers' prices of goods and services used by moderate-income city families advanced more rapidly in 7 of the 10 largest cities in the South than the national average for the 34 large cities usually surveyed for this purpose by the Bureau of Labor Statistics. Savannah, Jacksonville, New Orleans, and Norfolk—heavy shipbuilding centers—and Birmingham—the steel city of the South—were among the cities showing the largest increases. In Savannah and Jacksonville, consumers' prices rose more between the outset of war in Europe and June 1946 than in any other city surveyed, 41.6 and 40.5 percent, respectively. Retail prices in Memphis and Atlanta also advanced more rapidly than the national average; prices in Mobile increased only slightly less than the 34-city average. In Houston and Richmond—two cities on the edge of the South—the rises in prices were among the smallest for all large cities in the United States between August 1939 and June 1946. Table 42 shows the rise in consumers' prices in 34 large cities ranked by percentage change between August 1939 and June 1946. There is a difference of 12 percentage points between the southern city having the largest rise during this period and the southern city having the smallest rise.

---

[1] Prepared by Floyd C. Mann, of the Bureau's Prices and Cost of Living Branch.

[2] The South is defined here as including Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Kentucky, Tennessee, Arkansas, Louisiana, Oklahoma, and Texas.

[3] One measure of the impact of the war on southern cities is the number of southern cities designated as "congested areas" by the President's Committee for Congested Production Areas. Eight of the 15 production areas defined as congested were in the South. These were Charleston, S. C.; Mobile, Ala.; Brunswick, Ga.; Key West, Fla.; Hampton Roads, Va.; Knoxville, Tenn.; Pascagoula, Miss.; and Beaumont, Tex.

TABLE 42.—*Rise in Consumers' Prices in Large Cities, Ranked by Percentage Change Between August 1939 and June 1946*

City	Percent increase, August 1939 to June 1946	City	Percent increase, August 1939 to June 1946

Cincinnati, Ohio	35.9		
Cleveland, Ohio	35.7		
Washington, D. C	35.7		

Consumers' prices have risen less in Houston than in other large cities because of a smaller rise in the costs of food and clothing and a decline of almost 7 percent in fuel, electricity, and ice costs. Gas and electricity rates have dropped sharply in Houston since the fall of 1939. Meat prices have not risen as rapidly in Richmond as in most other large cities. This, combined with a less than average rise in residential rents, has resulted in Richmond being 1 of the 3 cities with smallest increases during the period.

Further evidence of the rapid rise of consumers' prices in the South as compared with other areas can be obtained from special surveys of prices in 13 small southern cities and war production centers conducted by the Bureau of Labor Statistics during the war period. Between mid-1940 and early 1945, the earliest and latest dates for which indexes are available for all 13 cities, prices advanced more rapidly than the national average in all but 1, and in 8, prices rose from 6 to 13 percentage points more than the average for the 34 large cities. Increases ranged from 25 percent in Stillwater, Okla., to 39 percent in Vicksburg, Miss., while during the same period—June 15, 1940, to March 15, 1945—consumers' prices rose only 26 percent on the average in 34 large cities throughout the United States. The second part of table 43 shows percentage changes in consumers' prices in selected southern cities for all items combined and each major group from mid-1940 to the spring of 1945.

Food prices, which represent approximately two-fifths of the moderate-income city families' budget, increased more rapidly in most southern cities than the national average for 34 large cities. Seven of the 10 largest cities had increases greater than the national average for the 7-year period August 1939 to June 1946; in 12 of the 13 selected southern cities and war production centers the increase in food prices between 1940 and 1945 was more than the average rise for all large cities.

Food prices in the South rose rapidly during the fall of 1941 and the early months of 1942 prior to the establishment of the General Maximum Price Regulation in May 1942. After that, further increases in the prices of uncontrolled items pushed the level of food prices to a wartime high in May 1940, before the President's "hold-the-line" order checked the advance. From that date through June 1946 food prices on the average remained stable. With the temporary removal of subsidies and price controls in mid-1946, food prices rose more in Atlanta and New Orleans between June 15 and July 15 than the national advance of 13.8 percent. For the other 8 large southern cities, the advance ranged from 9.3 percent in Mobile to 13.7 percent in Memphis.

Food shortages became progressively more severe in all large cities in the fall of 1944, and in the spring months of 1945 and 1946, but supplies in large southern cities were consistently smaller than in other regions. To some extent these shortages reflected the failure of distributors to alter their distribution of supplies in accordance with the shifts in population. From February 1943 through November 1945, the Bureau of Labor Statistics made surveys of food supplies in independent stores in 56 large cities. Throughout most of this period, food supplies were less adequate in the large cities in the Southeastern States than in any other region in the United States. In the spring of 1945, it was not uncommon to find 85 to 90 percent or more of the independent stores regularly visited without any meat.

The increase in clothing prices in southern cities, large and small, was less than the average rise for 34 large cities during the war. Increases ranged from 49 percent in Houston to 56 percent in New Orleans between August 1939 and June 1946, as compared with a national average of 57 percent. Between June 1940 and March 1945, clothing costs in Vicksburg and Goldsboro advanced almost as much as the national average (41 percent). In all other selected southern cities and war production centers, clothing prices rose less rapidly. About two-thirds of the rise in clothing prices in the South occurred before May 1943. However, continued shortages and the disappearance of lower price lines have been reflected in the steady advances in clothing costs since May 1943.

TABLE 43.—*Consumers' Price Changes in Large and Small Southern Cities and War Production Centers, August 1939 to June 1946 and June 1940 to March 1945*

City	All items	Food	Clothing	Rent	Fuel, electricity, and ice	Housefurnishings	Miscellaneous
	Percent change, August 15, 1939, to June 15, 1946						
Large southern cities:							
Savannah, Ga	+41.6	+63.9	+54.9	+11.3	+11.8	+71.8	+33.6
Jacksonville, Fla	+40.5	+57.4	+49.5	[1] +10.5	+22.6	+51.5	+40.0
Birmingham, Ala	+38.6	+62.8	+53.1	+10.0	+21.7	+50.0	+28.0
New Orleans, La	+38.4	+61.5	+56.2	+4.8	+7.7	+41.2	+24.7
Norfolk, Va	+38.2	+56.0	+52.0	+7.7	+23.8	+55.5	+33.6
Memphis, Tenn	+37.5	+71.2	+53.5	[1] +10.5	+12.1	+38.9	+20.2
Atlanta, Ga	+36.5	+52.4	+53.5	[1] +3.2	+19.8	+58.6	+37.5
Mobile, Ala	+34.8	+56.9	+52.6	[2] +9.8	+9.6	+43.4	+20.8

[1] Change to March 1946.
[2] Change to May 1946.
[3] Changes from June 15, 1940, to April 15, 1945.
[4] Estimated, based on changes in food, rent, gas, and electricity costs in this city, and on changes in other costs in large cities in U. S.
[5] Changes from October 15, 1940, to March 15, 1945.
[6] Changes from September 15, 1940, to March 15, 1945.

Residential rents rose more sharply in most large and small cities in the South than in all large cities in the Nation. Rents in 34 large cities combined advanced 4 percent on the average between the outset of war in Europe and June 1945; increases were greater than this in 7 of the 10 large southern cities, and in the heavy industry cities of Birmingham, Jacksonville, Memphis, and Savannah they advanced more than 10 percent. In Atlanta, Houston, and Richmond the increases in rents were less than the national average. Ten of the thirteen selected southern cities and war production centers had increases in residential rents greater than the national average from mid-1940 to March 1945. In Charleston, one of the most important shipbuilding centers of the South, rents jumped 12.7 percent during the 5-year period 1940 to 1945.

At the outset of war in Europe, southern cities in comparison with many large northern cities had a relatively small reserve of housing to accommodate additional population. The tremendous influx of war workers and their families in a wartime boom of employment quickly exhausted the small excess capacity that was available and augmented the pressures on already heavily strained facilities. The characteristics of the population increase in southern cities during the war were also significantly different from what would be expected under normal conditions, and these differences tended to intensify the congestion problem. Heavy Negro migration into urban areas that lacked adequate housing accommodations in 1940 compounded the overcrowding. A marked increase in the proportion of women in the southern cities also caused a greater strain than would otherwise have been the case. The range of housing accommodations acceptable to women is narrower than it is for men.

Residential rents rose rapidly in the early part of the war until rent controls were imposed and rents were rolled back to their 1941 or 1942 maximum rent dates. Birmingham, Jacksonville, Mobile, and the Norfolk area—all shipbuilding centers—were among the first cities in the Nation for which controls were established. Prior to the date at which the areas were brought under control, rents rose sharply for all types of housing, but the greatest increases were for those renting to whites at less than $30 per month and for those occupied by nonwhite tenants.

One measure of the severity of the housing shortage in the South during the war was the amount of public and private construction of housing for war workers that was allowed by a Nation conserving building materials for only the most essential needs. Between July 1, 1940, and September 30, 1945, Mobile and Norfolk increased their total dwellings by about 45 and 37 percent, respectively. During the same period, the total number of family accommodations completed with priority assistance in Savannah and Jacksonville amounted to 19 and 13 percent of their prewar housing facilities. Relatively large numbers of dwellings were also added in Atlanta, Houston, and New Orleans.

Contract monthly rents for tenant-occupied, privately financed residential dwellings rose sharply in many southern cities between the Census of Housing in April 1940 and the National Housing Agency dwelling surveys in 1945. The following tabulation shows the percentage increase in average monthly contract rents between 1940 and 1945 for a selected list of southern cities.[4]

	Survey date	*Percent increase, April 1940 to survey date*
Pine Bluff, Ark	May 1945	136
Charleston, S. C	April 1946	131
Brownsville, Tex	August 1945	130
Mobile, Ala	May 1945	66
Little Rock, Ark	April 1946	46
Newport News, Va	December 1945	46
Portsmouth, Va	December 1945	38
Louisville, Ky	November 1945	33
Knoxville, Tenn	November 1945	28
Dallas, Tex	May 1945	24
Norfolk, Va	December 1945	22
New Orleans, La	June–July 1945	17
Houston, Tex	November 1945	16

These percentage changes are based on the average contract monthly rent for rental dwellings at the time of each survey. They reflect in addition to changes in rents shown in the consumers' price index, changes in the size and type of dwellings, and changes in the services and household equipment included in the contract rent.

Statistics on the number of evictions from tenant dwellings show that there was no significant difference between the South and North in 1944 and June 1946. In spite of this fact, however, the problem was more acute in the South because of the intensity of the congestion in southern cities.

There were great increases in the number of dwellings occupied by owners throughout the United States during the war but the largest change in the proportion of owner-occupied dwellings between April 1940 and early 1945 occurred in the Southeastern States where the increase was 34 percent compared with 28 percent for 122 cities throughout the United States.

Changes in fuel, electricity, and ice costs varied sharply among the large and small southern cities during the war. In general, gas and electricity rates declined throughout the country and the South was no exception. Gas and electricity costs, which have more than usual importance in the budgets of families living in Houston, Corpus Christi, and Dallas, declined enough to cause an average decrease for the fuel, electricity, and ice group in these cities since the beginning of the war. These costs, taken as a group, rose on the average for all other cities surveyed except for Stillwater, Okla., where they remained unchanged.

---

[4] The rental data presented in this tabulation are not comparable with the figures on changes in rents given in table 43 of this section. The figures given in table 43 are based on the Bureau of Labor Statistics consumers' price index which reflects changes in rent charged for the same dwelling with the same services and facilities.

On the average, the cost of housefurnishings in the southern cities have risen less than the national average during the war, but the cost of miscellaneous goods and services in the South increased more than the average rise for 34 large cities combined.

City-to-City Comparisons

The over-all costs of equivalent goods, rents, and services important in the budgets of moderate-income families are slightly lower on the average in the large cities of the South than in other large cities throughout the country. The differences, however, are not great. Variations in costs among cities of the same size within the same region are greater than any differences found between regions. Relative differences in the cost of equivalent goods and services in the 33 large cities for which comparable figures are available for March 1945 are shown in table 44.

Living costs in the large cities in the South ranged from 88 to 95 percent as great as in Washington, D. C. (taken as the base or 100). Food prices were generally higher in southern cities than in Washington, but the cost of clothing, miscellaneous goods and services, and particularly housing was considerably lower in the southern cities than in Washington. Variations in requirements owing to climate were taken into account in making these comparisons. Thus, lower housing costs in southern cities are attributable in part to the smaller quantities of fuel needed for house heating and differences in requirements of heavy and light clothing also have some effect on comparative clothing costs.

Comparisons of March 1945 and prewar living costs show that the relative differences in the costs of equivalent goods, rents, and services in large cities in the South and in other large cities of the United States have been reduced.

The March 1945 comparisons show smaller percentage differences in costs among individual cities than indicated by estimates for the prewar years. Costs in nearly all of the large southern cities have moved up in relation to costs in Washington during this period. In the 8 southern cities for which data are available costs were 5 to 12 percent lower than in Washington; whereas in 1939 costs in these cities were from 10 to 15 percent below Washington. This tendency toward equalizing differences in costs is consistent with the greater rise in wartime prices in cities—particularly in the South—where costs were relatively low before the war.

The cost of identical food items in southern cities ranged from 98 percent of the Washington cost in Houston to 104 percent in Jacksonville and New Orleans. With the exception of Houston, where food costs were 2 percent lower, retail prices of identical foods were higher in all of the southern cities surveyed than in Washington in March

TABLE 44.—*Relative Differences in Cost of Equivalent Goods, Rents, and Services in Large Cities in the South and Other Selected Large Cities, March 1945*

[Costs in Washington, D. C.=100]

City	Total	Identical foods	Equivalent clothing	Housing: Average rental for 4- and 5-room dwellings with standard facilities; fuel, utilities, and housefurnishings [1]	Other

Seattle, Wash	103	109	96	83	117

[1] Includes rents for 4- and 5-room dwellings with standard facilities—kitchen with sink, hot and cold running water, private bath, electric lighting, and installed heating equipment—and relative costs of fuel, utilities, and housefurnishings. Dwellings reported as needing major repairs or located in neighborhoods containing specified hazards or nuisances were not included in the comparisons. This concept of comparable rental costs does not take account of differences in the supply of rental housing that would meet these standard specifications or in the availability of such housing for rent. Thus, in some cities there are many homes without indoor plumbing, and the proportion of homes with standard facilities is small. No account is taken of this fact.

[2] Medical care, personal care, recreation, transportation, automobiles, and durable goods. The effect of differences in prices of automobiles, mechanical refrigerators, and other durable equipment not available for pricing in March 1945 is estimated by assuming a continuation of prewar differentials in costs of these items.

1945. Costs of equivalent clothing, however, ranged from 6 to 14 percent lower in the cities in the South than in Washington.

Housing costs, which are based on average rents for dwellings with standard facilities and relative costs of fuel, utilities, and housefurnishings, were below the Washington level in all southern cities surveyed. Housing costs were lowest in New Orleans, where they were 34 percent below Washington in March 1945; they were 32 percent lower in Houston, and 23 percent lower in Savannah and Norfolk.

Other costs, which include medical care, personal care, recreation, transportation, automobiles, and durable goods, were below those in Washington in practically all southern cities.

IX.—State Labor Legislation in the South[1]

The purpose of this summary is to give briefly the principal provisions of labor laws now on the statute books of 13 Southern States.[2] No effort has been made to trace historically the development of labor legislation in the South. However, State action in this field did not become a vital issue in the region until about 1900, when interest in child labor legislation began to develop. The first child labor laws in the South were passed in 1903. Laws limiting the hours of labor of women in industry date, roughly, from 1909, and the beginnings of workmen's compensation legislation are found a few years later.

For many years, private organizations, groups of officials charged with administration of labor laws, and trade-unions have worked toward securing agreement on what constitutes adequate protection under labor laws. One of these groups is the International Association of Governmental Labor Officials—an organization of State administrators of labor law. A second is the International Association of Industrial Accident Boards and Commissions, which gives consideration to problems in the field of workmen's compensation. A third group, composed of labor law administrators and representatives of labor organizations appointed by the Governors of the States, called into annual conference by the United States Secretary of Labor for the past 12 years, has reached agreement on matters of policy and administration of labor laws.

The general thinking of these various groups is represented in a declaration of the Fifth National Conference on Labor Legislation. Every State, according to the recommendation of the conference, should have a department of labor under a full-time commissioner or commission to enforce its labor laws properly. The administration of all laws relating to labor should be centralized in such a department; its administrator should have authority to protect the safety and health of workers. The labor department should be provided with an adequate appropriation and with a trained and competent inspection staff selected on a merit basis to administer all its laws. The report further recommended that the labor laws of every State should make provision for at least the following: For all workers, compulsory workmen's compensation for accidents and occupational diseases; unemployment insurance; wage and hour standards; provision for prompt and regular wage payment and for the collection of unpaid wages by the labor department; and adequate child labor standards. In addition, the suggested labor code should make provision for public employment agencies and for the regulation of private employment agencies; for the control of industrial home work; and for machinery to handle industrial disputes by State mediation and voluntary arbitration boards and by State labor relations boards.

---

[1] Prepared by Charles F. Sharkey and Marian L. Mel, of the Division of Labor Standards, U. S. Department of Labor.

[2] The States are Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia.

No State fully meets these recommendations. Over the entire country there is the widest possible variation in the number and effectiveness of the labor laws which have been adopted. The recommended standards are here included because they provide, in a sense, a model code against which the actual development of labor legislation in these or in any other States may be examined.

State Labor Departments

All the Southern States, except Mississippi, have labor departments. In most of these States, however, some labor laws are administered by agencies outside such departments. In Alabama and Louisiana, for example, the workmen's compensation acts are administered by the courts. Agencies separate from the labor departments also administer workmen's compensation in Arkansas, North Carolina, Oklahoma, South Carolina, Texas, and Virginia. In this same group of States and in Tennessee, unemployment compensation is administered by separate agencies. The employment service is within the departments of labor only in Alabama, Arkansas, Florida, Georgia, Kentucky, and Louisiana. Coordination of administrative activity in the field of labor legislation clearly has not been fully achieved in the group of States under consideration.

No picture of the protection offered workers is complete without including the facts as to the size of the labor department appropriations, the extent of its staff, and other matters concerning administration which are not included in this article. Nevertheless, as the enactment of laws is basic in the protection of workers, a general picture of the status of labor legislation in any State may be gained by the following discussion of specific types of labor laws.

Hours of Work

The National Conferences on Labor Legislation recommend that all workers be protected as to working hours, suggesting, as a reasonable standard, an 8-hour day and a 40-hour week. Even in the war period of urgently needed production, nine Government agencies, including the War and Navy Departments, recommended that hours of work be kept as far as possible to 8 a day, 48 a week, and 6 days a week, as a means of insuring maximum efficiency. Limiting hours of work by requiring that increased hourly rates be paid after a basic number (daily and weekly) is the method employed not only in the Fair Labor Standards (Wage and Hour) Act and in the Public Contracts (Walsh-Healey) Act, but also in some State laws and in orders issued under authority of minimum wage acts.

None of the 13 Southern States has legislation for an 8-hour day, 48-hour, 6-day week with a broad coverage. Here, as in other sections of the country, limitations of hours for men are applied most commonly to occupations in which danger either to the worker or to the public is involved, as in the case of miners, railroad employees, or motorbus drivers. The employment of women is more generally covered.

Alabama does not regulate the hours of adults. An Arkansas law fixes a basic 8-hour day and 6-day week, with a requirement for overtime pay for women over 16 in practically all occupations. In Florida, any employee, in the absence of a written contract, is entitled to extra pay for all hours in excess of 10 a day. A Georgia law limits the hours of employees in cotton and woolen manufacturing establishments to 10 a day and 60 a week, with the exception of specific occupations. In Kentucky, a 10-hour day, 60-hour week applies to females in a fairly comprehensive list of employments, and the same standard covers all females under 21 in any gainful occupation except domestic service and nursing. A basic 8-hour day, 40-hour week on public works, with time and a half the prevailing wage rate for overtime, is the only regulation of hours applying to men. A Louisiana act of 1942 has an 8-hour day, 48-hour, 6-day week for females in a comprehensive list of industries; women in occupations not covered by this act are limited to a 9-hour day, 54-hour week.

In Mississippi, a 10-hour day, 60-hour week is the standard for females in any occupation, and the same provision exists for persons 16 years of age and over in mills and factories; in both cases overtime is permitted in case of emergency. A limit of 9 hours in 12, 48 hours a week, and 6 days a week in North Carolina protects only female workers of employers of more than 8 persons in any occupation; specifically exempted, however, are a large number of employments. Men are quite comprehensively covered by a 10-hour day, 56-hour week.

In Oklahoma, a 9-hour day, 54-hour week is limited to females in a comprehensive list of employments, with exemption of establishments employing less than 5 such workers in towns of less than 5,000.

South Carolina limits hours of females in mercantile establishments to 12 a day, 60 a week. Employees of cotton, silk, rayon, or woolen textile mills (with a number of exceptions) are covered by an 8-hour day, 40-hour, 5-day week. Enforcement of this law was at one time enjoined; but according to the commissioner of labor, the injunction has been dissolved. Tennessee limits women's hours in a number of occupations to 57 a week; Texas, to 9 a day, 54 a week. In Virginia, a 9-hour day, 48-hour week is limited to women in laundries, restaurants, and mercantile and manufacturing establishments.

DAY OF REST

Louisiana and North Carolina have laws requiring a weekly day of rest limited to women in enumerated industries. The South Carolina act establishes a 5-day week for employees in textile mills, and in Arkansas a permit must be obtained from the labor commissioner to work on the seventh day. Meal or rest periods of varying lengths are found in Arkansas, Kentucky, Louisiana, and North Carolina, applying generally to women or to women and minors.

Minimum Wage

Since the first minimum wage law was passed 34 years ago (1912), State minimum wage legislation has been enacted in 26 States, Alaska, the District of Columbia, Hawaii, and Puerto Rico. In only 4 States (Connecticut, Massachusetts, New York, and Rhode Island) and in Hawaii and Puerto Rico does the legislation cover men.

Minimum wage laws are of three types. One authorizes the department of labor, or a specified agency within it, to establish minimum wage rates recommended by wage boards. The second type establishes a minimum wage in the law itself. A third kind, an example of which is the law of Hawaii, follows the pattern of the Fair Labor Standards Act; the law establishes a specific minimum hourly rate and basic hours, with provision for increased hourly overtime rates, and provides for subsequent increases of the statutory minimum, based on wage-board action.

Traditionally, workers in service industries have been among the lower paid groups. As these are intrastate employments, no relief is offered by the Fair Labor Standards Act. On this situation, the Commissioner of Labor and Industry of Virginia commented in the biennial report issued in 1944:

> The adoption of minimum wage legislation on State level will prove of untold benefit in the postwar period to workers who do not have the protection of the Federal Fair Labor Standards Act. The responsibility for the protection of workers in intrastate occupations is with the State, and if this reponsibility is not assumed through State legislation their well-being will be seriously jeopardized. By neglecting to provide this protection for its citizens who are working without any protective wage contracts, the State will retard its social and economic progress, as employment under substandard remuneration reduces the standards of living and tends to involve the entire commonwealth in a downward spiral. Employees of industries engaged in interstate commerce have Federal legisla-

tive protection which prevents their wages being cut below a certain minimum standard. Why should not intrastate occupations be covered by wage orders? It can be expected that the transition from a war to a peace economy will be accompanied by a critical unemployment figure which will reduce the standard of living and decrease the demands for consumer goods. When this economic calamity attacks our wage structure, the States with minimum wage laws will be able to throw a life preserver to the marginal workers and will thus prevent wage cutting below health subsistence. Virginia should have a minimum wage law of general coverage.

Four, among the Southern States studied—Arkansas, Kentucky, Louisiana, and Oklahoma—have enacted minimum wage laws, and they apply to women or to women and minors. The Arkansas law, passed in 1915, applicable to women only, with specific industry coverage, establishes a statutory minimum wage of $1.25 a day for experienced workers. The minimum rate for workers with less than 6 months' experience is $1.00 a day. Time and a half pay is required after a basic 8-hour day and basic 6-day week.

In Kentucky, a minimum wage law of the wage-board type applies to women and minors. Under this authority a blanket order, covering all industries except laundry and dry cleaning and dyeing, provides for minimum wage rates ranging from 20 to 25 cents an hour, according to zone. A separate laundry, dry cleaning, and dyeing order establishes rates ranging, according to zone, from 20 to 28 cents an hour. A hotel and restaurant order passed subsequently to the blanket order provides for rates ranging from 20 to 30 cents an hour. Each order provides for payment of overtime rates.

The Louisiana law, which is also of the wage-board type, applies to women and girls. Although the legislation was enacted in 1938, no minimum wage orders have been issued to put the law into effect.

The Oklahoma law, also of the wage-board type, was written to cover men, women, and minors. The law has been declared unconstitutional as to its coverage of men and boys, owing to a defect in the title. Enforcement of the orders for women is prevented by injunction, so that the law is inoperative.

All four laws exclude agriculture; the Kentucky and Louisiana laws exclude domestic service. In Kentucky, persons subject to regulation by the public service commission, and in Louisiana, municipalities having a population of 10,000 or less, are not covered by the minimum wage acts.

Industrial Home Work

Only two States—Tennessee and Texas—in this group have homework laws.

Tennessee's law neither prohibits home work nor authorizes the department of labor to do so. Homes where specified kinds of work are performed must be reported to the board of health. Certain requirements are established with respect to cleanliness, light, and ventilation, and workplaces are subject to the supervision of the bureau of workshop and factory inspection. No licensing of employers is required, nor of home workers except in the case of minors under 16 years. Without licensing, enforcement is impossible.

Texas has a home-work law, though not under the jurisdiction of the department of labor. Authority is given to the State Board of Health to investigate any industry, and upon finding that industrial home work cannot be continued without injuring the health and welfare of the home workers, the board may prohibit home work in the industry. This law was passed in 1937, but by September 1946 no steps had been taken by the health department to put it into effect.

Under the home-work system, goods are given out by an employer to workers who perform one or more processes in their own homes and return the finished goods to the employer. The home worker usually furnishes the sewing machine or other equipment, collects and returns the materials, and is sometimes even charged for spoilage. The piece-rate method of payment prevails and low wages are universal. Long hours, night work, and the use of children of all ages are characteristic of industrial home work. Under these conditions, wage and hour and child labor laws become meaningless. Home work, therefore, represents an unfair type of competition to be met by the enlightened employer who has all his work performed in the factory, meets the obligations of law, and pays all overhead costs of production.

Conferences of home-work administrators have repeatedly recommended one of two courses of action: First, that States which do not have home work should, by law, make it impossible for the system to be introduced; in other States, legislation should empower the department of labor to prohibit home work, industry by industry. The few workers who, on account of age or disability, could never adjust themselves to factory work, may be permitted to continue working under certification by the proper administrative agency.

Wage Payment and Wage Collection Laws

Florida and Mississippi have no wage payment laws. A semimonthly pay day in Alabama applies only to employees of public service corporations engaged in transportation and employing 50 or more persons.

An Arkansas law requires a semimonthly pay day for employees of corporations; a second law forbids use of scrip or other token not payable on the next regular pay day; a third statute provides that employees of every company and corporation shall be paid on the day of discharge.

In Georgia, wages must be paid semimonthly in lawful money or check; excepted from the law are farming and sawmill and turpentine industries. The Kentucky semimonthly pay-day law applies to employees of corporations organized for profit; wages must be paid within 3 days to workers who are discharged or who quit. Another law requires employers of 20 or more persons to redeem scrip or other evidence of debt in legal tender at face value at least once a month on a regular pay day. A third measure, requiring payment in lawful money, applies only to wage earners employed by corporations or in factories, mines, or workshops.

In Louisiana, a semimonthly pay day is required for all employees (except the clerical and sales force) in manufacturing, mining, and oil boring, where 10 or more are employed, and in public service corporations. A second law, applying to all workers, requires that checks or other tokens be redeemed at face value, on demand, on the pay day following issuance; those employees discharged and quitting must be paid within 24 hours; if not, their wages continue until paid or payment is tendered.

In North Carolina, a law applying only to railroad-shop and roundhouse employees requires a semimonthly pay day and payment in lawful money or check. In Oklahoma, compulsory payment in lawful money is required for employees in mining, quarrying, manufacturing, and transmission and transportation of passengers or freight and, if demanded, a semimonthly pay day. In South Carolina, a weekly pay requirement applies to textile manufacturing and a semimonthly one to shop employees of certain railroads; nonnegotiable pay orders are prohibited except for agricultural employees under contract. Tennessee private employers of 20 or more must pay semimonthly in lawful money or check. A Texas law with broad but by no means complete coverage requires a semimonthly pay day, and payment within 6 days after demand for discharged or quitting workers and those absent on pay day. In Virginia, certain railroad employees and employees in mining and manufacturing are entitled to a semimonthly pay day and payment in lawful money or check or cash order. Employees of sawmills and excelsior mills must be paid monthly.

In the States covered, as in many others, the absence of a protective law on wage payment or the existence of a poor one makes workers the victims of financially irresponsible or careless or, in some cases, dishonest employers. The recognized standard for wage payment and wage collection laws includes the following guarantees: The worker must be able to count on the payment of his wages in full, in actual money (not scrip or other substitute), on regular pay days. The pay period should be short enough so that living expenses can be met on a cash, not a credit, basis. Prompt payment of wages due should be guaranteed to a worker who is separated from the pay roll. The State labor department should be authorized to help a worker collect wages due, if his employer fails or refuses to pay him.

Industrial Safety and Health

At conferences dealing with labor legislation it has been agreed that safety of workers is the responsibility of the employer and it has been recommended that he should be required by law to furnish a safe workplace. For many years, labor laws attempted to spell out the specific standards which would safeguard workers against industrial accidents and diseases. It is now generally agreed that because changing methods of production bring about changing hazards, a different approach is needed.

The Second National Conference on Labor Legislation, held in North Carolina more than 10 years ago, advocated that "the State department administering the labor laws should have authority to formulate industrial rules or codes, preferably with the assistance of advisory committees, including representatives of employers, employees, and experts, for the protection of the health and safety of employees. Such rules or codes should conform substantially to nationally approved standards."

Many States in preparing safety and health standards have adopted in whole or in part the safety codes promulgated by the American Standards Association.

STATUTES AND REGULATIONS

In all the States covered in this article, except Mississippi, the departments of labor have definite responsibility under law for insuring the safety of workers. The labor departments of Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, North Carolina, and Oklahoma have statutory authority to issue regulations for the safety and health of workers. In Tennessee, the department has such authority for industrial safety only. In South Carolina, as in Mississippi, rule-making authority is given to the department of health. In Texas and Virginia, although limited statutory standards exist, no general power to issue safety and health regulations exists in any agency.

As of 1946, action had been taken under such authority as follows:

The Alabama Department of Industrial Relations has issued a basic safety manual which includes, together with rules dealing with common accident hazards, basic information on accident prevention. In addition, other rules cover mine safety and open pits and quarries.

The Arkansas Commissioner of Labor has issued a basic safety manual, covering practically the same subjects as those in the Alabama manual, and five additional codes dealing with special subjects. The Alabama and Arkansas codes follow the American Standards codes very closely.

Under the authority of the Florida Industrial Commission, five codes dealing with various branches of the lumber and woodworking industries and also with boiler safety have been adopted.

In addition to the adoption of certain safety rules by the Kentucky Department of Industrial Relations, a comprehensive list of safety codes promulgated by the American Standards Association has been recommended to employers.

No rules have been issued in Georgia or in Louisiana under the authority of the commissioners of labor.

Under authority of the commissioner of labor, North Carolina has issued a basic safety code and 10 or more special codes. Oklahoma has adopted safety rules on 15 subjects.

The Tennessee Division of Factory Inspection, in carrying out its authority to prescribe safety devices and safeguards, has issued more than 40 rules covering various subjects. A 1945 act of the State Legislature transferred the functions of the department of labor, with respect to conditions injurious to the health of industrial workers, to the department of public health.

In Mississippi and South Carolina, rule-making authority is vested in the State Board of Health.

Workmen's Compensation

Workmen's compensation laws are designed to assure prompt payment of benefits to injured employees or to the dependents of those killed in industry, regardless of fault. In the early days, if an injured worker sued his employer for damages, he had to prove that the employer was negligent. Under the compensation law the question of fault or blame for the accident is not raised, as the cost of work injuries is considered part of production costs.

Workmen's compensation laws are of two types—compulsory and elective. A compulsory statute is one whereby every employer within the scope of the compensation law is required to accept the act and pay the compensation specified. An elective act is one in which the employer has the option of either accepting or rejecting the act, but in case he rejects it he loses the customary common law defenses—assumed risk of the employment, negligence of fellow servants, and contributory negligence. The compulsory type of law has been recommended by the several National Conferences on Labor Legislation.

All the States in the group considered, with the exception of Mississippi, have enacted workmen's compensation laws. Of these

States, only four—Arkansas, Kentucky, Oklahoma, and Virginia—have compulsory laws; however, the Kentucky and Oklahoma laws cover only hazardous employments. The laws of the other States are elective. In Georgia, North Carolina, and South Carolina the laws are compulsory for public employees, and in Texas for operators of motorbusses.

The employer is required in each of these States to obtain insurance with private insurance companies, or to give proof of his ability to carry his own risk (self-insurance). In Oklahoma, employers may insure their risks in the State insurance fund or with private carriers.

COVERAGE

None of the 47 States conform entirely to the suggested standards with respect to coverage as recommended by the National Conferences on Labor Legislation.

The suggested standards for workmen's compensation acts include total coverage of workers regardless of the type of industry or the number of employees and require the payment of benefits not only in the case of an accidental injury, but also for disabilities resulting from an occupational disease.

All of this group (except Louisiana) provide that employers of fewer than a stipulated number of employees are exempted from compensation-coverage requirements. Although the Louisiana act does not have a numerical exemption, coverage is limited in this State because the law applies mainly to listed "hazardous" or "extra-hazardous" employments. None of these States covers agricultural or domestic service. However, most of the acts permit voluntary acceptance by the employer in these fields, and also in instances in which there is a numerical exemption or in which the law applies only to hazardous employments.

OCCUPATIONAL DISEASE

The National Conference on Labor Legislation has frequently recommended "general" coverage of occupational disease instead of "schedule" coverage under which compensation is paid only for specifically listed diseases. A similar recommendation was made by the International Association of Accident Boards and Commissions in 1944. Occupational disease legislation has been enacted in six of the States in this group—Arkansas, Florida, Georgia, Kentucky, North Carolina, and Virginia—but only Florida provides general coverage. The Kentucky law is limited to silicosis and injuries or death by gas or smoke in mines and by poisonous gas in any occupation.

BENEFITS

The compensation benefits are based on proportion of wages received by the injured worker. In death cases, these percentages sometimes vary and depend on the number of children. The suggested standard as recommended by the National Conference on Labor Legislation proposes that in disability cases not less than 66⅔ percent of the employee's wages should be paid as compensation, and that the maximum weekly compensation should be based on a standard of living above the subsistence level. In the group of 13 States the maximum percentage of wages in disabilities ranges from 50 to 66⅔ percent, although in recent years there has been some improvement in the maximum weekly payments permitted by these laws. These payments still do not take into consideration the higher wages now paid. The maximum weekly payments vary from $18 in Alabama, Kentucky, and Tennessee to $25 in South Carolina. In Arkansas, Georgia, Louisiana, Texas, and Virginia the maximum is $20, in North Carolina and Oklahoma $21, and in Florida $22.

The National Conferences on Labor Legislation have recommended that death benefits be paid to the widow for life (or until remarriage), and to children until they reach the age of 18. However, none of the listed States has such provisions. In all these States the death benefits are limited to payments for a specified period ranging from 300 to 450 weeks. Oklahoma pays no death benefits. Some of these States also fix a total maximum for death benefits ranging from $5,000 to $7,200. With respect to permanent total disability, it has been recommended that benefits be paid during the period of disability, but in the States under consideration, such benefits are limited as to time and amount, or both. The time periods range from 350 to 550 weeks, and the money limits from $5,000 to $10,500.

Permanent partial disabilities are classified as specific or schedule injuries, such as the loss or loss of use of a member, and "nonschedule" injuries, which are those of a more general nature, as, for example, disability caused by injury to the head or back. The measure of such compensation is usually a stated number of weeks. In Arkansas, Florida, Georgia, and North Carolina, the compensation for permanent partial disability is in addition to the period of total disability or healing period. In Alabama, Kentucky, Louisiana, Oklahoma, South Carolina, Tennessee, Texas, and Virginia, on the other hand, the schedule payments are exclusive; in other words, the temporary total benefit payments are subtracted from the amount due from permanent partial disability. In either event, there may be money or period limitations.

MEDICAL CARE

In all workmen's compensation acts, medical care is required to be furnished to injured employees. In early legislation the provision for medical aid was narrowly restricted as to monetary cost, period of treatment, or both. In the later development of the acts such absolute restrictions have been changed in many cases either by providing for unlimited benefits or by authorizing benefits in addition to the initial maximum upon the approval of the administrative authority. In Arkansas, Florida, Georgia, North Carolina, Oklahoma, and South Carolina, medical benefits are virtually unlimited because the administrative agency can extend such services indefinitely. In Arkansas, however, there are arbitrary limitations upon the medical aid for occupational diseases. In Alabama, Kentucky, Louisiana, Tennessee, Texas, and Virginia, there are period or cost limitations. Extensions are permitted in Tennessee, Texas, and Virginia, but these are restricted to specified periods or amounts, or both.

WAITING PERIOD

All the States in this group provide for a specified waiting period immediately following the injury during which compensation shall not be paid. This "waiting time" is 3 days in South Carolina, 4 in Florida, 5 in Oklahoma, and 7 days in the other States. The justification for the waiting period is the cost and administrative burden of bookkeeping in setting up claim files and accounts where but a few dollars are involved. The waiting period relates only to compensation. Medical and hospital care are provided immediately, regardless of the fact that compensation is not paid for a specified period. Most of the laws provide that if the disability continues for a certain number of weeks the payment of compensation is retroactive to the date of injury. In Arkansas, Kentucky, North Carolina, Tennessee, and Texas, if the disability lasts for 4 weeks, compensation is paid from the date of disability. In South Carolina, the retroactive period is 2 weeks; in Louisiana and in Virginia it is 6 weeks. There is no retroactive period in Alabama, Florida, Georgia, and Oklahoma.

SECOND-INJURY FUNDS

In recent years, a new type of provision establishing "second-injury funds" has been included in workmen's compensation laws. When an employee has sustained an injury involving the loss of a member of the body and then loses another as a result of an industrial injury, he may become permanently and totally disabled. If the total cost of compensation is imposed on the latest employer, physically handicapped persons are apt to be refused employment. To meet such problems second-injury funds were created, so that when a second njury occurs the employer has to pay only for the last injury, yet the mployee is compensated for the disability resulting from the combined njuries, the remainder of the award being paid from the fund.

State workmen's compensation commissioners, employer and employee groups, and veterans' organizations have agreed that second-injury funds offer the best means of facilitating the employment of disabled veterans and other handicapped persons. The International Association of Industrial Accident Boards and Commissions, at its meeting in September 1944, recommended a draft bill relating to second injuries and the establishment of a second-injury fund. The draft bill provides that, if an employee who has sustained one of certain specified losses (i. e., the loss, or loss of use, of one hand, one arm, one foot, one leg, or one eye) becomes permanently and totally incapacitated through the loss, or loss of use, of another member or organ, the employer shall be liable only for the compensation payable for the second injury, and the balance of the compensation shall be paid out of the second-injury fund. The fund is financed by payments of $500 by the employer in each case of death if there are no dependents.

Second-injury funds have been established in Arkansas, Kentucky, North Carolina, Oklahoma, South Carolina, and Tennessee. The laws of Arkansas, North Carolina, South Carolina, and Tennessee conform to the standards proposed by the draft bill with respect to the injuries covered, although differences exist in the methods of financing the fund. The Kentucky law applies in the case of an employee who previously was permanently partially disabled, and who receives a second injury whereby the combined disabilities are greater than that which would have resulted from the second injury alone. In Oklahoma, the law applies to "physically impaired persons" who receive a second injury which results in additional permanent disability.

MINORS

All workmen's compensation laws cover minors legally employed. In Arkansas, Georgia, Kentucky, North Carolina, South Carolina, Texas, and Virginia, compensation is paid to minors illegally employed on the same basis as if they were legally employed. In Alabama and Florida, the laws provide extra compensation in such cases. On the other hand, the laws of Louisiana, Oklahoma, and Tennessee do not cover minors illegally employed.

ADMINISTRATION

In establishing the workmen's compensation system the principal objective was to provide a simple, convenient, and inexpensive method of settling the claims of injured workers. Both the National Conferences on Labor Legislation and the International Association of Industrial Accident Boards and Commissions have recommended administration by a commission or board rather than by the courts. In most of the Southern States having workmen's compensation laws, special agencies have been formed to administer the acts. However, in Alabama, Louisiana, and Tennessee, court procedure remains as a survival of early practice.

Industrial Relations

Industrial-relations legislation in the group of Southern States has been limited generally to the fields of conciliation, mediation, and arbitration of industrial disputes, and to the regulation of unions and labor-organization activity.

CONCILIATION, MEDIATION, AND ARBITRATION

Most of the Southern States are authorized by law to endeavor to settle disputes through the use of conciliation, mediation, or arbitration machinery.

Conciliation and mediation services are provided through special permanent agencies in two State labor departments—in North Carolina, the division of conciliation, and in Oklahoma, the board of arbitration and conciliation.

In six other States, authority to mediate or to promote voluntary conciliation or mediation is vested in a designated government official. This official is the labor commissioner in Arkansas, Georgia, Louisiana, and South Carolina, and the commissioner of industrial relations in Kentucky. In Alabama, the Governor is empowered to appoint mediation boards, and the department of industrial relations is also authorized to promote mediation.

Five States—Florida, Mississippi, Tennessee, Texas, and Virginia—have no machinery for conciliation and mediation of labor disputes.

Arbitration under special procedures for labor disputes is provided for in Alabama, Arkansas, Georgia, Louisiana, North Carolina, Oklahoma, South Carolina, and Texas. Permanent arbitration agencies are established in the labor departments of two of these States—the North Carolina Arbitration Service and the Oklahoma Board of Arbitration and Conciliation.

PROTECTION OF LABOR'S RIGHTS

There is a limited amount of legislation, in these 13 States, protecting labor's right to organize and bargain collectively.

The right of organization and collective bargaining is recognized by law in Alabama, Florida, and Kentucky. The Alabama law, however, also specifies the right of employees to refrain from such activities. One State, Louisiana, has an anti-injunction law modeled after the Federal Norris-LaGuardia Act, and an Oklahoma law places limited restrictions on the courts in labor disputes.

Blacklisting of employees is forbidden by law in seven States—Alabama, Arkansas, Florida, North Carolina, Oklahoma, Texas, and Virginia; and "yellow dog" contracts are outlawed in Louisiana.

UNION REGULATION

Over the past 5 or 6 years, there has been a decided increase in State legislation restricting or regulating union activity. At present, all these States except five—Kentucky, North Carolina, Oklahoma, South Carolina, and Tennessee—have union regulatory laws. Many of these laws have been held invalid, and others are in process of appeal in the courts, so that the constitutionality of much of this legislation is still in doubt. The main provisions of those laws still in effect are summarized as follows.

Internal Union Organization

Alabama, Florida, and Texas adopted legislation in 1943 which regulates internal union organization. The Alabama act requires every labor organization to file with the State department of labor copies of its constitution and bylaws, and the secretary and business agent of every local union with 25 members to make annual verified reports to its members and to the labor department, containing data on its officers, membership, elections, and property holdings, and a complete financial statement. It also prohibits membership of professional or supervisory employees in labor organizations which admit or are affiliated with unions admitting nonsupervisory employees, and forbids collection by a labor union of any fee for a work permit.

The Florida Union Regulatory Act prohibits interference with the right of franchise of any union member and solicitation of membership without authority of that organization. With regard to union finances, the law limits union initiation fees not in effect in 1940 to $15, requires unions to keep itemized financial accounts open to the membership, and prohibits unions from requiring payment of back dues of returning servicemen.

The Texas Union Regulatory Act requires every union to file with the secretary of state copies of its constitution and organization records and to make annual verified reports to the secretary of state containing data on the organization, its affiliates and locals, its local officials, its property holdings, and a complete financial statement.

The Texas law also establishes citizenship requirement for union officials, provides that union members may be expelled only for good cause and after public hearing, and directs the courts to intervene to reinstate any member expelled in violation of these provisions.

Unions are forbidden to collect fees for work permits, to make political contributions, or to require returning servicemen to pay back dues, and are required to keep itemized financial accounts open to the membership and to legal proceedings. The legal requirement that union organizers secure a registration card from the secretary of state was held unconstitutional in a case appealed to the United States Supreme Court.

Right to Work

So-called "right to work" constitutional amendments have been adopted in Arkansas and Florida. The Florida amendment makes unlawful the denial of the "right to work" on account of membership or nonmembership in any labor organization. The Arkansas amendment authorizes legislation of this type.

Strike, Picketing, and Organization Activity

Eight States—Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, Texas, and Virginia—have laws directly regulating unions during strikes, picketing, or other organizational activity.

Participation in "wildcat" strikes is outlawed in Alabama. Florida forbids strikes unless authorized by majority vote in a secret ballot and prohibits seizure or unlawful occupation of property during a labor dispute. It also forbids strikes caused by jurisdictional disputes. A Georgia law requires 30 days' written strike notice of all employees except seasonal and railroad workers. Louisiana in 1946 adopted legislation providing that "wildcat" strikes in violation of collective-bargaining agreements are against public policy.

So-called "anti-violence" legislation, recently adopted in Alabama, Arkansas, Mississippi, and Texas, outlaws assemblage near the place where a labor dispute exists and forbids the use or threat of force to prevent any person from engaging in a lawful vocation. The Alabama law also outlaws the use of threats, force, or coercion to prevent an employer's use of materials, equipment, or service. Violation of this legislation in Arkansas, Mississippi, and Texas is made a felony.

A Florida law outlaws picketing the home of an employee, picketing beyond the area of the industry in which a dispute arises, picketing by force or violence or in such manner as to prevent entrance to or exit from any premises, or picketing "other than in a reasonable and peaceable manner."

The following acts are prohibited by Virginia law: Interference with the right of another to work; use of force, threats or intimidation, or insulting language to induce any person to quit his employment or to refrain from seeking employment; picketing by force or violence; picketing so as to interfere with the entrance or exit of any premises or of the free use of public streets; and picketing by any person not employed by the business picketed, either at that time or immediately prior to the strike.

Unemployment Insurance

In the Southern States studied the unemployment-insurance laws differ considerably as to coverage and amount of benefits, the duration of unemployment, and other factors. Ten States—Alabama, Florida, Georgia, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia—provide that employers of 8 or more employees in 20 weeks are covered by the legislation. Arkansas specifies 1 or more employees in 10 days, Kentucky 4 or more employees in 3 quarters of a preceding year, and Louisiana 4 or more employees in 20 weeks.

After an unemployed worker has filed a claim and before benefit payments begin, a waiting period of 1 or 2 weeks is usually required. All the States in this group have 1-week waiting periods except Georgia and Mississippi, which require a 2-week period before benefits begin.

In order to be entitled to benefits, a worker must have earned a specified amount in covered employments. The amount of the benefit to be paid is determined by the worker's wages or employment during a "base period." This period, generally 1 of the 4 quarters of the year (13 weeks), is used to determine a worker's earnings for eligibility, weekly benefits, and the duration of benefits. Under most laws the worker receives approximately 50 percent of his full-time weekly wage. All States limit the maximum and the minimum amount of weekly benefits.

In this group, the top limit on benefit payments ranges from $15 to $20 a week. Alabama, North Carolina, and South Carolina pay a maximum of $20; Georgia, Louisiana, Oklahoma, and Texas, $18; Kentucky, $16; and in Arkansas, Florida, Mississippi, Tennessee, and Virginia, the maximum is fixed at $15 a week. Minimum payments range from $3 to $6 a week. The maximum number of weeks in which unemployment-compensation benefits are paid ranges from 14 to 20. Benefits are limited to 14 weeks in Mississippi, to 16 in Arkansas, Florida, Georgia, North Carolina, South Carolina, Tennessee, and Virginia; and to 20 weeks in Alabama, Kentucky, Louisiana, and Oklahoma. Texas alone has specified that instead of a definite number of weeks the payment should be 9 times the benefit allowed for a 2-week period.

Child Labor

The following review of the major provisions of the child labor laws shows the existing standards.

MINIMUM AGE

North and South Carolina, in 1937, became the first of the Southern States to incorporate a 16-year minimum age standard in their child labor laws. Florida followed in 1941, Louisiana in 1942, and Georgia in 1946. Four of these five States—Georgia, Louisiana, North Carolina, and South Carolina—have a 16-year minimum age for employment in factories at any time and for any employment during school hours except in agriculture and domestic service. The fifth State—Florida—also has a 16-year minimum age for factory employment at any time, but requires a minimum age of 14 for all other employment during school hours.

A 15-year minimum age requirement obtains in factory and related employment in Texas. A 14-year minimum age standard applies to factory employment at any time in the remaining seven States (in Kentucky only during school hours), and to all other work during school hours, except in Mississippi, Oklahoma, and Virginia. In Virginia, work in agriculture and, in Mississippi and Oklahoma, work in agriculture and certain other occupations are not covered.

For work outside school hours most of these States set a minimum age of 14 but usually exempt agriculture and domestic service, and some permit employment at the age of 12 in certain other occupations. A few establish no minimum age for nonfactory employment outside school hours or cover no work outside school hours.

EMPLOYMENT CERTIFICATES

Because the employment certificate shows that the minor for whom it is issued has reached the minimum age for work and has met the other requirements fixed by law for his protection, an employment certificate system is a safeguard against illegal employment and an essential support of child labor standards. Ten States in this group require employment certificates as a condition for the employment of minors under 16 years of age, and seven States require either employment certificates or age certificates for minors above this age (Alabama to 17, and to 19 for work in certain hazardous employments; Florida, Georgia, Louisiana, and North Carolina to 18; Oklahoma to 18 where continuation schools are established; and Tennessee to 18 in certain hazardous occupations).

The child labor laws of three of the States, however, do not provide for an employment certificate system (Mississippi, South Carolina, and Texas). To supply the need for proof of legal employment under the child labor provisions of the Fair Labor Standards Act in these States, certificates of age are issued by the U. S. Department of Labor in cooperation with State and local officials. Moreover, in all 13 States, age certificates are issued for minors who have passed the age when certificates are required, on request of the minor or the employer.

HAZARDOUS OCCUPATIONS

In general, the protection from hazardous employment afforded minors under age 18 in the listed States is inadequate, particularly as to minors 16 and 17 years of age. Only three States (Louisiana, North Carolina, and Virginia) now prohibit employment of minors of 16 and 17 in any considerable number of dangerous occupations. Greater protection is afforded children under 16 from hazardous work, more than half the States prohibiting their employment in many hazardous occupations. Little or no such protection, however, is given in several States.

MAXIMUM HOURS AND NIGHT WORK

None of the 13 States protects minors up to 18 years of age from excessive hours of work to the extent recommended by the International Association of Governmental Labor Officials—a maximum 8-hour day, 40-hour week, and 6-day week. Louisiana, which has an 8-hour day, 44-hour week, and 6-day week for minors under 18, comes nearest. Few of the other States have limited maximum hours for both boys and girls of 16 and 17.

Five States, in addition to Louisiana, have adopted for children under age 16 a maximum workweek standard of less than 48 hours. These are Florida, Georgia, and North Carolina, with an 8-hour day, 40-hour week for children under 16, and Mississippi and Virginia with an 8-hour day, 44-hour week, for such children. Except for South Carolina, the remaining States have an 8-hour day, 48-hour week, applicable to children under 16 (in Texas to children under 15). South Carolina has no maximum hours of work provisions applicable to minors only, but has an 8-hour day, 40-hour week, 5-day week[3] for most employees of any age in silk, rayon, cotton, and woolen mills. For girls in stores the maximum is a 12-hour day, 60-hour week.

All 13 States have prohibited night work of minors under 16 years of age, but only 4 (Arkansas, Florida, Louisiana, and North Carolina) have such a prohibition for both boys and girls 16 and 17 years of age.

---

[3] See comment under Hours of Work (p. 119).

STANDARDS AND ACCOMPLISHMENTS

Looking at the child labor laws in the States analyzed as a whole, the most serious weaknesses are the frequent exemptions of agriculture and domestic-service occupations, in which large numbers of children are employed; the lack of protection afforded minors 16 and 17 years of age, both in respect to hours of employment and to hazardous work; the limited coverage of some of the older laws; and the lack of certificate systems in three of the States.

In the South, as in the entire country, war labor needs brought about an unprecedented demand for the employment of young workers. This demand is reflected in the large increases in the number of employment and age certificates issued for children between 14 and 18 years of age during the war years, although these certificates do not tell the whole story. They do not cover children going to work in all industries, they are not required for all young workers of these ages, and they do not, of course, reflect illegal employment.

Even with these limitations, the figures are striking. In 11 of this group of States for which reports are available for both 1940 and 1945, the number of young persons between 14 and 18 years of age obtaining employment or age certificates for work (full time or part time) increased more than sevenfold. About 17 percent of these boys and girls going to work in 1945 were 14 or 15 years of age. Available figures for 1946 indicate a decided drop, as would be expected with the cessation of war demands, but in general the totals for the first 5 months of 1946 are considerably above those for the entire year 1940.

Although child labor legislation has developed slowly in this region, noteworthy advances have been made in the past decade in the laws of a number of the Southern States. These gains meet or approach standards urged as desirable for the employment of young persons by the International Association of Governmental Labor Officials and other groups interested in the protection of young workers from harmful child labor and reflect a sincere recognition of the needs of the young people of this region. The standards recommended by the International Association of Governmental Labor Officials are a 16-year minimum age for factory employment at any time, 16 for all employment during school hours, 14 outside school hours for all nonfactory employment, and for minors under 18 years of age a maximum 8-hour day, 40-hour week, and 6-day week; prohibition of night work; a requirement of employment certificates; and prohibition of work in hazardous occupations.

X.—Social Security in the South[1]

Social security, in the broad sense, has become a recognized responsibility of the Federal Government. The tremendous number of persons in need during the depression following 1929 demonstrated the inability of the average individual to provide against prolonged economic adversity, as well as the inability of most States to meet adequately the situation created by the depression. Under the Social Security Act, passed in 1935, two general systems of benefit payments were authorized, one based on insurance contributions and the other on the need of the beneficiaries.

Insurance against certain economic hazards can be based on past earnings in industry. Monthly benefits (as well as lump-sum payments) were provided under the act and the 1939 amendments thereto by the Old-Age and Survivors Insurance program for persons 65 years of age or over (and for certain of their dependents) who have worked in covered industry and have qualified for the payments. This is a wholly federally operated undertaking. An unemployment insurance system was set up as a joint Federal-State program providing unemployment benefits to those workers who have qualified while working in covered employment. There are other government operated or supervised social insurance systems, as well as staff retirement programs which are not operated under the Federal Social Security Act. These include the retirement systems of the Federal, State, and local governments, the workmen's compensation laws of the Federal and State governments, and the various insurance programs for railroad workers administered by the Railroad Retirement Board.

The programs of public aid in which the Federal Government participates are based on the need of the recipients and are administered by the States with grants-in-aid from the Federal Government for three types of needy persons: (1) Those over 65 who pass the State tests of need; (2) children, living with relatives, deprived of parental support as a result of death or incapacity of one or both parents; and (3) the needy blind. Other types of needy persons must be cared for wholly by State or local funds.

While present programs of social security are limited in terms of benefits provided and coverage, a genuine beginning has been made in giving some protection to substantial segments of the population against important economic dangers in modern industrial society. This is perhaps particularly noteworthy with respect to the Southern

The social security data used in this article have been previously published or were made available by the Social Security Administration of the Federal Security Agency. The cooperation of this Agency is gratefully acknowledged.

States, where per capita incomes are relatively low and the social security increment has been a significant addition. It is the purpose of this section to describe the operation in the South of the two insurance programs established under the Social Security Act.

Operation of the Old-Age and Survivors Insurance Program

COVERAGE

Under the Old-Age and Survivors Insurance program persons aged 65 or over, who have qualified by working for certain periods in employment covered by the law, may retire and receive monthly benefits. The worker's wife if aged 65 or over and/or his dependent children under age 18 may also receive monthly benefits. Lump-sum payments or monthly benefits are also provided for certain dependent survivors of insured workers. Generally, persons working for wages or salaries are covered by the act, with a number of important exceptions. The major exceptions are agricultural labor; domestic service; casual labor not in the course of the employer's business; service performed for the worker's child, spouse, or parent; certain maritime service performed on vessels of foreign countries; employment for Federal, State, and local governments; employment for religious, charitable, and certain other nonprofit organizations; railroad employment; and self-employment.

From its inception until June 1945, over 82 million persons, representing 62 percent of the population on July 1, 1945, had established accounts with the Bureau of Old Age and Survivors Insurance of the Federal Security Agency. Of this number, about 21 million, or approximately 55 percent of the population, were in the Southern States. The following tabulation shows the number of accounts established by employees under old-age and survivors insurance, cumulative from November 1936 through June 1945, and the percentage these employees formed (July 1, 1945) of the total population of the United States and of the southern regions.

	Accounts established[1] *(in thousands)*	*Percent of population*[2]
Total, United States	82, 229	62. 3
Southern States	20, 701	55. 2
Southeastern States	13, 205	54. 1
Southwestern States	7, 496	57. 4
All other States	61, 528	65. 1

[1] Federal Security Agency, Social Security Bulletin, August 1945 (p. 33).

[2] Population data from Bureau of Census, Special Reports, Series P–46, No. 3. These percentages are somewhat overstated because the data do not eliminate duplicate account numbers, nor have adjustments been made for deaths of account holders. These percentages are not the proportions of the population covered by the act at any particular time because account numbers are issued to all workers who apply, regardless of whether their employment is covered under the act. As a result, the number of persons actually covered is considerably less than the number of accounts, since many workers with account numbers and at some time in covered employment are not presently so engaged, while others with account numbers have never worked in covered employment.

Of the 46.3 million persons who worked in covered employment at some time during 1944, 9.5 million were in the South (table 45). The South's proportion of covered workers was therefore considerably smaller than its share of the country's population. This relatively smaller coverage of workers is a reflection of the greater proportions of persons in noncovered employments—agriculture, domestic service, and self-employment, including farming.

During 1940, the first year that monthly benefits were awarded, 43,338 persons in the Southern States and 211,646 in the remainder of the country were awarded benefits. As of June 30, 1946, there were 1,700,696 monthly beneficiaries in the whole country, of whom 300,228 were in the South. The southern proportion of the total number of beneficiaries (17 percent in 1940 and 18 percent in 1946) was somewhat smaller than that of workers in covered employment. This reflects, partly, the younger median age of the population in these States,[2] but, to a greater extent, the fact that in these States covered employment constitutes a smaller proportion of total employment and consequently relatively fewer workers are insured.

TABLE 45.—*Old-Age and Survivors Insurance: Workers in Covered Employment, United States and Southern Regions* [1]

[2] Figures do not necessarily add to totals because of rounding.

BENEFITS

To be eligible for benefits a worker must have worked in covered employment for certain periods, with earnings of at least $50 in each period, prior to his death or his attaining the age of 65.[3] Under certain conditions of eligibility the wife and children of an insured worker and certain surviving dependents may draw benefits. The amount of each type of benefit [4] is obtained by applying appropriate fractions to the wage earner's primary benefit amount. This latter amount is based on the worker's wage history and is derived by using a single benefit formula.

---

[2] In 1940, 7.4 percent of the population of the non-Southern States were 65 years or older, while only 5.4 percent of the people of the 13 Southern States were that old.

In measuring the regional differentials in average benefits each type of benefit should be studied separately, since the difference in average total benefits is distorted by the dissimilarity between the South and the rest of the country in the proportions of the various types of benefits. The greater prevalence of large families in the Southern States leads to a much higher proportion of child's benefits in this region than in the rest of the country. On the other hand, primary benefits are considerably less important in relation to total benefits than in the other States.

The average monthly amount of benefits in force in the South, June 30, 1946, ranged from $10.62 for a child to $21.63 for the primary beneficiary. At that date the average child's benefit in the rest of the country was $13.15 and the average primary benefit was $24.94. (See table 46.) There have been no marked changes in the differentials in types of benefit payments during the past few years.

Adequacy of Old-Age and Survivors Insurance in the South

The benefits paid out under the old-age and survivors insurance program have brought real economic relief to aged workers and their families and to surviving dependents. This is particularly true in areas where incomes are meager and the old-age benefit is often the only source of income. Nevertheless, the operation of the program

---

[3] In general, a worker is fully insured if he has received $50 or more in wages for covered employment in half the quarters elapsing after 1936 (or his twenty-first birthday if it is later) and up to the quarter in which he reaches age 65 or dies. A minimum of 6 quarters is necessary. After a worker has 40 quarters of coverage he is permanently fully insured, regardless of whether he is in covered employment thereafter. Prior to 1947 a worker was currently insured if he had wage credits of not less than $50 for each of not less than 6 of the 12 quarters immediately preceding the quarter in which he died. For claims applications filed after 1946, a worker is currently insured if he received $50 or more in wages for covered employment in 6 quarters of the period consisting of the quarter of death and the 12 preceding quarters.

[4] The primary benefit is paid to a fully insured retired wage earner aged 65 or over. The wife's benefit, equal to one-half the primary benefit amount, is paid under certain conditions to the wife, aged 65 or over, of a primary beneficiary.

The child's benefit, equal to one-half the primary benefit amount, is paid under certain conditions to the child of a primary beneficiary or a fully or currently insured deceased worker.

The widow's benefit, equal to three-fourths the primary benefit amount, is paid under certain conditions to the widow, aged 65 or over, of a fully insured worker.

The widow's current benefit, equal to three-fourths the primary benefit amount, is paid under certain conditions to the widow of a fully or currently insured worker, provided she has in her care a child of her deceased husband entitled to child's benefits.

The parent's benefit, equal to one-half the primary benefit amount, is paid under certain conditions to he dependent parent of a fully insured deceased worker.

Table 46.—*Old-Age and Survivors Insurance: Average Monthly Amount of Benefits in Force,*[1] *by Type of Benefit, June 30, 1946* [2]

Region	Average monthly amount of benefits in force						
	Total	Primary	Wife's	Child's	Widow's	Widow's current	Parent's
United States	$18.97	$24.48	$12.92	$12.49	$20.20	$19.93	$13.05
Southern States	15.59	21.63	11.30	10.62	18.40	17.40	11.76
Southeastern States	15.42	21.56	11.33	10.47	18.30	17.13	11.51
Southwestern States	15.97	21.78	11.21	10.96	18.65	17.98	12.48
All other States [3]	19.70	24.94	13.15	13.15	20.43	20.63	13.45

[3] Includes Alaska, Hawaii, and Foreign.

falls far short of the good it could accomplish if its benefits were increased and its coverage extended Such extensions would have particular significance in the Southern States, where State and local finances are often insufficient to care adequately for aged workers and their dependents.

In 1940 the number of beneficiaries under OASI represented 0.12 percent of the total population in the South as compared with 0.22 percent in the rest of the country. As of June 30, 1945, 0.61 percent of the population in the South were monthly beneficiaries, compared with 1.12 percent in the rest of the country. Conceivably, with an increasingly older population, about 8 to 12 percent of the population of the non-Southern States may become recipients of benefits under OASI. Without an extension of coverage, however, not much more than about 4 to 6 percent will receive benefits in the South.

Only about 1.2 percent of the people aged 65 or over in the South were beneficiaries in 1940. This compared with 1.9 percent in the country as a whole. As of June 30, 1946, the aged beneficiaries in the Southern States were 6.3 percent of the population aged 65 and over as compared with 10.4 percent for the country as a whole. If no extension of coverage is enacted, eventually, when at least half the aged population in the country is receiving benefits, perhaps a fourth in the South may be doing so.

Even though the average wage benefit formula has been devised to give greater relative benefits to those whose wages during employment were in the lower brackets, primary benefit amounts are lower in the South then in the rest of the country. This is so not only because wage rates are lower but also because a greater proportion of all covered workers have worked part of the time in noncovered employment and thus cannot have all their earnings counted in the computations of their benefits.

An extension of coverage to farm workers, domestic servants, and the self-employed (the latter would cover the numerous farm owners or tenants in the South) would go far to remove the differential in coverage between the South and the other States.[5] The differential in benefits due to lower earnings will not change as long as earnings are lower in the South. There is sufficient justification, however, for increasing the level for the whole country. The increase in cost of living has made the problem one of pressing importance.

Operation of Unemployment Compensation Laws

COVERAGE

The Social Security Act imposed a national pay-roll tax of 3.0 percent on most commercial and industrial employers, but it permitted 90 percent of the tax to be offset by employers who paid an unemployment compensation tax to a State with an approved unemployment compensation law. The Federal tax encouraged the passage of State laws which are the basis for the administration of unemployment compensation. All States but one have set the tax on employers at 2.7 percent—90 percent of the Federal tax—while a few States have a tax on the wages of employees. Forty-five States have adopted experience ratings which reduce the tax for many employers, chiefly on the basis of their experience in payments of benefits to former employees. Since 1939 the Federal tax has been applied only to the first $3,000 paid by an employer to any one individual, and the States have also limited their tax to this amount.

The Federal unemployment tax applies to employers of 8 or more persons in at least 20 weeks during a calendar year, and does not cover certain categories of workers—those engaged in agriculture, domestic service, government, nonprofit organizations, and railroads.[6] Many of the State laws exclude the same employers as the Federal law; but more than half the States cover smaller business, and some cover a few kinds of work not subject to the Federal tax.

The cost of administering the various unemployment laws is borne by the Federal Government and is covered by the excess of the payroll tax above the credit allowed the States. Under the provisions of the Federal law the States have had wide latitude in the administration of the unemployment compensation laws. They determine the coverage of the laws, the amounts of benefits to be paid, the conditions for the payment of benefits, and the general policies of administration. The Federal law imposes certain responsibilities on the Federal Government and sets forth certain requirements which the State systems must meet.

---

[5] In 1940, 36.5 percent of the labor force in the South were farmers, farm workers, or domestic servants. In the other States only 14.1 percent were in these occupations.

[6] Unemployment compensation for railroad employees is administered separately under the Railroad Retirement Act.

During 1945, 42.5 million persons worked at some time in employment covered by State unemployment laws; for the 13 Southern States combined the comparable total was 9.1 million (but this latter figure includes some duplication because of persons earning wages in more than one Southern State during the year). This coverage, for the country as a whole, increased from 31.9 million in 1940, with 6.7 million (including duplication) in the South (table 47). These figures, however, include many persons who worked for only short periods in covered employment and failed to earn sufficient wages to qualify for benefits.

The figures on average employment covered by State unemployment laws are somewhat closer to the number of persons who would qualify for unemployment compensation by reason of meeting the requirements with respect to the amount of earnings. (In the United States as a whole, average covered employment is estimated to be about 10 percent below the number of "insured" workers.) Average monthly employment in covered industry in the United States rose from 23.1 million in 1940 to a peak of 30.0 million in 1944. The proportion of this employment in the Southern States remained fairly constant, about 17 percent, over the period, rising from 3.9 million in 1940 to 5.3 million in 1944 (table 48).

Considerably fewer persons qualify as eligible for unemployment benefits because of failure to meet all the State eligibility and qualifying requirements. The number of beneficiaries depends not only on the number who earn sufficient wages in covered employment in the base period, but also on the workers being actually fully or partially

TABLE 47.—*Unemployment Compensation: Workers With Wage Credits, United States and Southern Regions, 1940–45* [1]

[1] Source: Federal Security Agency, Social Security Administration. For years prior to 1940, data are average weekly number of payments during month. For the years 1940 through June 1946, data are average weekly number of beneficiaries. From July 1946 through December 1946, data are average number of beneficiaries during weeks ended in month.

[2] Includes estimates for California and South Dakota.

Benefit rights may be canceled or reduced by certain disqualifications for workers who might otherwise be eligible to receive them: For voluntarily quitting, for discharge for misconduct, for refusal to accept suitable work, and for stoppage of work due to labor disputes, benefits may be denied from 1 week to the duration of the unemployment, or they may be reduced for all or part of the duration.

The various eligibility and qualification requirements result in the disapproval of a considerable number of claims. Many other claimants return to work before receiving a single benefit payment. While only 63.8 percent of new claimants in 1946 ever became beneficiaries, the 13 States in the South show a still stricter record: with 11 of these States below the national average, 5 had less than 50 percent of the new claims approved (table 50).

TABLE 50.—*Unemployment Compensation: Proportion of New Claimants Who Became Beneficiaries, 1946, United States and Southern States* [1]

State	New claimants, total	Beneficiaries receiving first payment

BENEFITS

By December 31, 1946, over 10 billion dollars had been paid into the State accounts of the unemployment trust fund held by the Federal Treasury, representing contributions collected and interest accumulated. Of the total fund, 1,383 million dollars was in the accounts of the 13 Southern States. By that date 3,716 million dollars had been paid out in benefits of which 406 million was for the 13 Southern States. In these States the ratio of benefits to collections plus interest was 29.3, while in the other States it was 36.0. The somewhat smaller ratio of benefits to collections and interest in the Southern States reflects the fact that these States generally have greater restrictions in the payment of benefits and that the average benefit is smaller in amount and duration.

The conditions under which workers may receive benefits and the amounts they may receive are specified by the various State laws.[7] A worker's eligibility for benefits and the amount which he may receive in a 12-month period is determined by his record of employment and wages during a past period. Table 51 shows, for the Southern States, the maximum duration and maximum amount of benefits in effect at the end of 1945 as well as the average weekly benefit for total unemployment in 1940 and in September 1946. In no case does the average benefit equal that for the country as a whole. Increases in benefits during the period were roughly equivalent to increased earnings.

Adequacy of Unemployment Compensation in the South

Only 10.7 percent of the civilian population in the South was employed in covered industry in an average week in 1940, compared with 20.2 percent in the rest of the country. By 1944 these proportions had increased to 15.5 percent and 26.6 percent, respectively. The greater relative increase in the South results from the greater relative increase in manufacturing employment in that area, along with a greater decrease in farm population.

TABLE 51.—*Unemployment Compensation: Selected Data on Benefits, United States and Southern States* [1]

Region and State	Statutory minimum number of workers for employer coverage [2]	Maximum benefits [2]		Average weekly benefit for total unemployment	
		Duration in weeks	Weekly benefit amount	1940	September 1946
United States				$10.56	$18.27
Southeastern States:					
Virginia	8 or more in 20 weeks	16	$15	7.68	13.42
North Carolina	8 or more in 20 weeks	[3] 16	20	4.68	12.41
South Carolina	8 or more in 20 weeks	[3] 16	20	6.71	14.16
Georgia	8 or more in 20 weeks	[3] 16	18	6.56	13.63
Florida	8 or more in 20 weeks or $5,000 quarterly pay roll.	16	15	9.72	13.62
Kentucky	4 or more in 3 quarters of preceding year to each of whom $50 is payable in each such quarter; or 8 or more in 20 weeks.	[3] 20	16	7.88	11.46
Tennessee	8 or more in 20 weeks	[3] 16	15	7.48	12.81
Alabama	8 or more in 20 weeks	20	20	6.52	15.75
Mississippi	8 or more in 20 weeks	[3] 14	15	6.03	12.39
Southwestern States:					
Arkansas	1 or more in 10 days	16	15	6.36	13.12
Louisiana	4 or more in 20 weeks	20	18	8.02	15.29
Oklahoma	8 or more in 20 weeks	20	18	9.84	16.37
Texas	8 or more in 20 weeks	18	18	8.07	14.81

[2] Coverage in effect on June 30, 1945. An employer becomes subject to the State unemployment insurance law when he has employed the specified minimum number of workers on at least 1 day in each of the specified number of weeks within the current or preceding calendar year.
[3] Uniform duration of benefits.

---

[7] See Unemployment Insurance in section on State Labor Legislation in the South, p. 134 of this bulletin.

The exclusion of farmers and workers in agriculture as well as domestic service from the State unemployment compensation laws is the most important reason for the relatively smaller coverage in the South. Other exclusions (principally railroad workers, employees of the various governments, maritime workers, and employees of small employers) brought the percentage of the total labor force covered by unemployment compensation to 31.6 in the South in 1940 as compared with 49.0 for the country as a whole.[8]

An estimated 2 million workers were excluded from coverage in the country in 1944 owing to the exclusion of small employers.[9] This restriction was particularly important in the South, where 10 of the 13 States covered only firms with 8 or more workers. Only 13 of the remaining 35 States have such a high size-of-firm requirement. The presence of numerous firms of fewer than 8 employees complicates the administration of the law in the cases of workers who change from employers who are not covered to those who are.

Of the 27 States which provide maximum benefits of $20 or more per week, only 3 are in the South, while of the 22 States which provide a minimum of $6 or more per week, only 1 is in the South. Likewise, as to the duration of benefits, 32 States provide duration of benefits for 20 weeks or more, but only 4 are in the South. Only 3 of the Southern States had average benefits in September 1946 of $15 or more, while 29 of the remaining 38 States had average benefits of this amount.

XI.—Development of Trade-Unionism in the South[1]

There has been a measure of trade-union activity in the South since the 1880's, and there were isolated instances of the existence of labor organizations prior to that time. During the past 60 years, union organization and membership in the South has risen with every major upsurge of organized labor activity nationally. Since 1900 a continuous labor movement, confined during much of the time to certain of the skilled crafts, has functioned in the region. After more than a decade of effort beginning with the NRA period, union organization has established itself in the southern iron and steel, coal mining, shipbuilding, petroleum refining, pulp and paper, and tobacco industries, and has penetrated cotton textiles, hosiery, and furniture. Lumber workers remain largely unorganized. The more traditional areas of organization, in construction, printing, railroading, longshore work, and the like, have been materially strengthened.

No complete account of the development of the labor movement in the South has been written; indeed, much basic research remains to be done before a definitive history can be prepared. The purpose of this section is to present the main outline of the story as an aid to perspective in viewing current developments in labor organization in the region.

The Knights of Labor in the South

The Noble Order of the Knights of Labor was founded in Philadelphia in 1869 by an obscure group of garment workers. Its membership climbed slowly to 71,000 in 1884 and skyrocketed to 730,000 two years later. The organization became, for a brief period, the chief vehicle of labor protest against the conditions that attended the rapid spread of industrial capitalism in the United States during the latter part of the nineteenth century.

Assemblies[2] of the Knights were organized in Alabama and Kentucky as early as 1879, but membership was not appreciable in the region until 1884.[3] During the next 4 years, the movement spread rapidly. The first assembly in North Carolina was formed in June 1884;[4] by 1887 assemblies had been organized in most of the counties of the State.[5] Incomplete data for 1888 show 487 assemblies in 10 Southern States, including 101 in North Carolina, 65 in Louisiana, 64 in Alabama, 56 in Kentucky, and 54 in Virginia.[6] Meyers estimates that the membership of the Knights in 10 Southern States was about 30,000 in 1886.[7]

---

[1] Prepared by H. M. Douty, Chief of the Bureau's Labor Economics Staff.

[2] The "assembly" was the unit of organization. Assemblies were composed of workers in one calling or else were "mixed"; i. e., composed of workers in various occupations and industries. Most of the assemblies in the South were of the latter type.

[3] Frederic Meyers: The Knights of Labor in the South (in Southern Economic Journal, April 1940, p. 483).

[4] H. M. Douty: Early Labor Organization in North Carolina, 1880–1900 (in South Atlantic Quarterly, July 1935).

Although the strength of the organization was most pronounced in the larger cities, local assemblies were scattered throughout the region. The poorer farmers contributed substantially to the membership of the Knights. Mitchell writes that of "112 assemblies in Alabama, Georgia, North and South Carolina which wrote in to the weekly journal [of the Knights] in 1888, 47 said their members were mainly farmers, 3 had mostly cotton mill hands, and 62 either had a mixture of farmers and artisans or did not state the composition."[8] Some effort was made to reach colored workers: there were a number of Negro assemblies in the South and some assemblies included both Negroes and whites. The Order was officially opposed to race discrimination.

According to its minute book,[9] Local Assembly No. 3606 in Raleigh, N. C., agitated for the 10-hour day, helped to conduct national boycotts, brought in speakers on labor subjects, encouraged study among its members, aided financially distressed brothers, and attempted to influence legislation. The movement touched many people with its message of the worth and dignity of labor and of the benefits of solidarity.

In a number of communities, cotton-mill operatives were organized. A long work stoppage took place at Augusta, Ga., where some 4,000 mill workers were out for about 2 months in an unsuccessful wage dispute. Other disputes involving cotton-mill workers occurred at Cottondale, Ala., Greenville, S. C., Maryville, Tenn., and Roswell, Ga. There were coal strikes in 1888 at Whiteside, Tenn., and at Pratt Mines, Ala. Sugar workers struck at Schriever, La., in 1887 and lumber workers at Ray, Ala., in 1890. The Knights also started many cooperative enterprises[10] in the South and participated actively in politics in some areas.

The Knights of Labor reached its greatest strength nationally in 1886, and thereafter declined rapidly. The peak in the South came a year or so later, but the decline was equally sharp. The town elements drifted away, and the remnants of the farm membership were attracted by the great Populist movement that developed in the region during the 1890's.

[10] Most of these enterprises were short-lived, but some lasted for a number of years.

Beginnings of Permanent Unionism Under American Federation of Labor

Almost a decade passed between the flurry of organization under the Knights of Labor and the second period of active union effort in the South. The American Federation of Labor, completely overshadowed by the Knights in the 1880's, managed to survive the deep depression of the nineties. Its membership was about 272,000 in 1897; under the stimulus of rising prices and generally prosperous business conditions, membership expanded to 1,556,000 in 1903. During this period, the Federation established a narrow base in the South.

Samuel Gompers became interested in the organization of southern workers as early as 1894.[11] At the American Federation of Labor convention in 1898, the executive council was instructed to place organizers in the southern area. Mr. Gompers was able to report to the 1899 convention that the "workers of the South are manifesting their appreciation of our efforts by forming unions, and uniting with our fellow workers in all parts of the country."[12] The convention instructed the executive council to take additional measures to stimulate organization in the South.[13]

For 3 or 4 years following 1898 labor activity was substantial in the South. Many groups of skilled workers formed local unions and affiliated with the national union of their craft.[14] The movement on the railroads, among the building trades, and in printing was highly significant. Some of these locals survived the decline in activity that occurred after 1902, combined into State federations of labor, and formed a permanent base for the labor movement in the region.

While skilled workers were rapidly forming unions, organization reached the factory employees and the Alabama coal miners. Little headway was made in the tobacco manufacturing industry. Locals of the International Tobacco Workers' Union were formed in North Carolina, Kentucky, and perhaps elsewhere in the South, but most of these locals quickly disintegrated. The union complained bitterly of the opposition of the "Tobacco Trust."[15]

The movement in cotton textiles was more vigorous and appeared first in Augusta, Ga., where the mills, late in 1898, announced a wage cut. The workers formed local unions and affiliated with the National Union of Textile Workers. This union had so few northern members that the southern workers found themselves in a majority. Prince Greene of Columbus, Ga., was president from 1898 to 1900, and secretary-treasurer from 1900 until the next year, when the United Textile Workers' Union was formed.

[12] A. F. of L. Proceedings, 1899 (p. 9).

[13] Idem (p. 65).

[14] In North Carolina in 1901, for example, there were 26 locals of building trades workers, 13 of railroad workers, 8 in printing, and 11 locals of other types of skilled workers. See North Carolina Bureau of Labor and Printing, Annual Report, 1901 (pp. 386 ff.).

[15] E. Lewis Evans: Tobacco Workers (in American Federationist, September 1903).

When the wage cut was made effective in Augusta, the operatives in 8 mills struck. The workers eventually returned at the lower rate, but on the basis of no discrimination against the strike leadership and with several minor concessions from the employers. Moreover, the union was able to maintain itself in the Augusta area.[16]

In the meantime, textile locals appeared in North and South Carolina, with the employers resorting to lock-outs to destroy union organization.[17] The decisive test in North Carolina occurred in the fall of 1900, when a strike lasting more than a month affected all of the mills in Alamance County. The strike, which had its origin in a minor incident, developed into a major fight for the right to organize. Evictions, the lack of adequate relief, and a slow market for cotton goods caused the strike to collapse.[18] The defeat broke the back of cotton-mill unionism in the Carolinas.

On April 1, 1901, President Gompers of the American Federation of Labor arrived in Danville, Va. The textile local there had decided to attempt to gain the 10-hour day.[19] When shorter hours were refused, the operatives walked out. The strike lasted for a number of weeks, but ended in defeat for the men. After the Danville defeat, union membership in the South was again confined to the Augusta district. In the fall of 1901, the Augusta locals attempted to obtain a 10-percent wage increase. Ultimately, about 7,000 operatives were directly involved. The newly organized United Textile Workers contributed funds for the relief of the strikers and aided in other ways. The strike was unsuccessful, the Augusta locals were broken, and thus ended the first substantial movement for cotton-mill unionism in the South.

The United Mine Workers entered the Alabama coal fields not long after its formation in 1890. By 1902, some 65 percent of the Alabama miners were organized. Many of the operators entered into collective-bargaining agreements with the union. A strike occurred in 1904 when some of the companies refused to deal with the union.

The real test of union strength came 4 years later, when the remainder of the operators refused to renew the union agreement.

---

[16] Mitchell, op. cit. (pp. 27 ff.).

[17] It is known that lock-outs occurred in Greenwood, Abbeville, and Bath, S. C., and at Greensboro and Fayetteville, N. C.

[18] Holland Thompson: From Cotton Field to Cotton Mill (New York, Macmillan Co., 1906) pp. 193–195.

[19] Apparently as a result of union agitation, the mill, which had been operating 12 hours daily, had announced late in 1900 that from January 1 to April 1 the schedule would be 10 hours, with 11 hours for the remainder of the year. The workers wanted a flat 10-hour schedule.

The union struck on July 6, 1908, and the stoppage lasted for about 2 months. Negro miners made up a substantial proportion of union membership in Alabama. White and colored miners exhibited marked solidarity during the struggle, but the race issue, raised by the companies, contributed greatly to the defeat of the strike.[20]

Quiescent Years, 1902–14

Union activity in the South between 1902 and the World War I period was confined largely, although not entirely, to the skilled trades. The period was not spectacular. There were many minor victories and numerous minor defeats for the skilled workers in unions. No major disputes occurred. Tangible improvement in economic position was secured in many situations as the result of persuasion or strike.

An indication of what happened may be furnished by random instances in North Carolina in 1906 and 1907. In the former year, the clerks of Salisbury organized and secured the earlier closing of stores; tinners in Charlotte won the 9-hour day; the printers in Wilmington gained an 8-hour day; a wage increase of 10 percent was secured by the machinists of Goldsboro. In 1907, the Asheville plumbers struck for the 8-hour day and compromised on 9 hours; the carpenters in Canton won the 9-hour day; in Wilmington, a cotton mill reduced hours from 11 to 10 when the employees, with the support of the local craft unions, asked for the reduction; the carpenters in Raleigh struck unsuccessfully for the 9-hour day.

These instances of union effort could be multiplied many times for the South as a whole. Taken together, their effect was not inconsiderable in the gradual improvement in labor standards that occurred in the region and in the remainder of the country during the decade preceding World War I.[21] There are no reliable estimates of union membership in the South during this period. It is certain that membership was relatively small.

A short but dramatic union episode during this period involved the lumber workers of the Southwest. The Brotherhood of Timber Workers, an independent union, was formed in 1910.[22] At the peak of its activity, this union had a membership of about 35,000 in the lumber industry of Texas, Louisana, and Arkansas. About half of the members were Negroes. In 1912 the union affiliated with the

[20] Sterling D. Spero and Abram L. Harris: The Black Worker (New York, Columbia University Press, 1931), pp. 355–359.

[21] The improvement reflected gains made through collective bargaining and through State labor legislation. Between 1903 and 1909, for example, every State in the South passed child labor laws.

[22] The formation of the Brotherhood of Timber Workers had been preceded by a largely spontaneous strike over wages in 1907 among the timber workers of Louisiana and eastern Texas. Industrial Workers of the World, The Lumber Industry and Its Workers (p. 76).

Industrial Workers of the World. Employer opposition was bitter, and the efforts of the union to secure improvements in wages and working conditions were punctuated by lock-outs, strikes, and violence against union members. Jensen writes: "The union began to crack when some of the most obnoxious causes of dissatisfaction, such as payment in scrip and forced use of company stores and monthly payment of wages, were modified and small wage increases and shorter hours were granted. At the same time, the strain of blacklisting, discrimination, and fomenting of racial conflict had an effect. After 3 years of struggle, the union had been completely destroyed." [23]

There was also a measure of organization during this period; some desperate strikes occurred among the cigar workers of Tampa; and, toward the end of the period, signs of restiveness among the textile workers began to appear. In 1912, the American Federation of Labor held its convention at Atlanta, which had the effect of stimulating interest in unionism in the South. In cotton textiles, locals were formed during 1912 at Danville and Lynchburg, Va., and at Knoxville, Tenn. A long stoppage in Atlanta in 1914 gave the movement valuable publicity, and an excursion during the same year by the IWW into the industry at Greenville, S. C., served to point up the workers' grievances.[24]

War Boom and Postwar Collapse, 1914–22

During World War I, manpower shortages, rising prices, and a governmental policy favorable, on the whole, to the labor movement lent impetus to the growth of union organization. Conditions were generally conducive to the extension of unionism until the sharp depression beginning in mid-1920.

The economic impact of the war upon the United States was felt long before the country entered the conflict. Unionization, especially among skilled workers, increased at a rapid rate from 1915 onward. The movement among factory workers did not get under way significantly in the South until a year or two later.

The marked increase in organization among craft groups in the South was accompanied by numerous strikes. Most of these stoppages were on a small scale, but some, as in the case of the street-railway employees in Charlotte and Winston-Salem, N. C., and Greenville, S. C., developed into long and bitter struggles. Many of the strikes during the early part of the period were over the 8-hour day issue; later, as living costs began to rise, wage disputes were frequent. Union recognition was often one of the points at issue.

[23] Vernon H. Jensen: Lumber and Labor (New York, Farrar & Rinehart, 1945), p. 91. See also Spero and Harris, op. cit. (pp. 332–333).

[24] Mitchell, op. cit. (pp. 32–35).

Aside from lumber and furniture, which remained relatively untouched, union activity penetrated deeply into the industrial life of the South during the First World War. Organization was extensive in tobacco, textiles, iron and steel, coal mining, and other industries.

TOBACCO INDUSTRY

In 1915, 3,245 members voted in a referendum to elect officers of the International Tobacco Workers' Union.[25] The only strength possessed by the union at this time was in a number of small factories (some of which were located in Kentucky) that catered to the union-label trade. The union had no influence among the workers in the major companies. Indeed, the union at this time was completely dependent upon the union label for tobacco products for its existence.

Beginning in 1916, locals of the union were formed in plants of the major companies, largely in the metropolitan New York area. Some of these locals were established during the course of unorganized strikes for wage increases and shorter hours.[26] Successful strikes and increased membership affected the character of the union. The use of the union label as an organizing device was largely discarded in favor of direct appeals to the workers to organize to improve their living standards.

In 1918, a number of short, spontaneous strikes occurred at the Durham, N. C., plants of the American Tobacco Co. and Liggett & Myers. A few of the workers sent for a union organizer. As a result, "a union was formed for the first time among the tobacco workers of Durham."[27] The companies resisted vigorously, however, and the union local was short-lived.

In Winston-Salem, N. C., the union met with greater success. In March 1919, the employees of the R. J. Reynolds Tobacco Co. began to organize. Membership increased rapidly. Despite some opposition from the Negro middle class of the community, colored workers joined in large numbers. By early summer, six large locals of tobacco workers had been established. On August 4, 1919, after much negotiation and the threat of a strike, R. J. Reynolds, Brown & Williamson, Bailey Bros., and Taylor Bros. signed an agreement providing for the 48-hour week, a 20-percent wage increase, and time and a half for overtime.[28] This union agreement represented the first ever signed by a major tobacco company in the South.

On the basis of its Winston-Salem success, the union reentered Durham and reached into Reidsville, where the American Tobacco Co. had a plant. In both cities, an appreciable membership was built up. Organizing activity was carried on for brief periods in other southern communities. The Winston-Salem victory was not repeated, however, and even in Winston-Salem the union's efforts to hold its membership were ineffective. By 1922, the membership of the union had been reduced to its prewar level.

COTTON-TEXTILE INDUSTRY

During the war and postwar boom, a very substantial union movement developed in the cotton-textile industry. Large numbers of workers were recruited and many strikes and some lock-outs occurred. The union was able to secure concessions at some mills and undoubtedly exerted material influence on conditions of work within the industry during this period. The vigorous unionism that developed, however, failed to survive the sharp collapse in business activity in 1920–21.

The United Textile Workers was active among the South Carolina cotton-mill operatives during 1915 and 1916. Mills in Greenville County were especially well organized and an appreciable membership was built up at other points in the State. The discharge of union members was the immediate point at issue in some of the disputes that took place at Greenville, Anderson, Columbia, and Westminster during this period. In 1917, major activity shifted to Georgia. The most noteworthy event was the organization of the industry in Columbus. A strike in this city resulted in a partial victory for the union in a settlement finally effected through the War Labor Board.

Mitchell writes of the period 1913–18:

> Early in 1919 the union's [United Textile Workers] activity in the South underwent so many changes that it is well to regard the years from 1913 to the end of 1918 as forming a distinct period in the development of the movement. Perhaps the chief characteristic of these 5 years was the confinement of unionism to the immediate vicinity of the places in which disputes concentrated the union's forces. The union did not have enough outside financial assistance to enable it to throw a network of organizers through the region. Possibly its strategy was to give its entire attention to each strike situation, in the hope that one substantial victory would make the union's position stronger than many quick failures. As for membership, it signed the workers by hundreds, and sometimes, as at Greenville and Anderson and Columbus, by thousands in the particular places in which it happened to be engaged; but at no time did the movement show a disposition to extend beyond the areas within easy reach of the organizers who were leading strikes.[29]

In the sense that textile union activity penetrated wider areas, 1919 appears to differ from 1918 and earlier years. Organization reached North Carolina and spread rapidly there, and South Carolina and Georgia continued to be centers of union activity. The 48-hour week had become a crucial demand. Early in 1919, strikes over the 48-hour issue took place at widely scattered points in the South; in several of these cases the workweek was reduced from 60 hours to 55 hours and other mills made this same reduction voluntarily.

---

[29] Mitchell, op. cit. (pp. 40–41). During the 1913–18 period, according to Mitchell, the United Textile Workers chartered about 40 locals in the South.

Union membership increased rapidly in North Carolina during 1919. At the convention of the State Federation of Labor in August, the claim was made that 30,000 workers had joined the union during the preceding few months.[30] By September, 43 locals had been chartered by the United Textile Workers in North Carolina.[31] The impetus to organization in North Carolina apparently came from a relatively successful strike growing out of local issues in Charlotte. In February 1919, a number of North Charlotte mills removed a wartime bonus of 35 percent of wages. Operatives in the weave room of one of the mills walked out and called in union organizers.[32] The strike spread. Finally, a settlement was negotiated which provided for the reinstatement of all workers without discrimination as to union affiliation; the 55-hour week; incorporation of the bonus in the wage bill; and free house rent for the duration of the strike. Union recognition was not achieved. A similar settlement was made after a lock-out of 1,500 workers in East Charlotte.[33]

The settlement made in Charlotte was satisfactory enough to those involved to enable the union to hold its membership. Indeed, the union obtained members at other mills in the Charlotte area not affected by the dispute, and the gains made in Charlotte were broadcast in mill communities throughout the State. The growth of the movement in North Carolina was accompanied by a whole series of strikes, many of which resulted in improved conditions for the strikers. Organization flowed over into the hosiery industry in High Point. In addition to Charlotte, stoppages occurred in cotton mills in Concord, McAdensville, Albemarle, Mooresville, Salisbury, Raleigh, Gastonia, and elsewhere in the State during 1919.

It was during this period that the United Textile Workers, for the first time, was able to point to substantial achievements in the form of reductions in hours, increases in wages, and some improvements in working conditions. Had the prosperity of the textile industry continued for a period of years, the union might possibly have entrenched itself strongly in the South. However, it is not at all certain that this would have happened, even if prosperous conditions had continued, because employer opposition was vigorous and many of he workers, who rushed into the union under the spur of specific rievances, tended to lose interest when these grievances were adjusted. n North Carolina, for example, the declining vitality of the movement was apparent in 1920. Membership slowly dropped away, despite the persistent efforts of a corps of organizers. The sharp depression beginning in 1920 and continuing through 1921 provided the occasion for the virtual disappearance of union strength.

[30] News and Observer (Raleigh, N. C.), August 12, 1919.
[31] Mitchell, op. cit. (p. 47).
[32] Observer (Charlotte, N. C.), February 26–28, 1919.
[33] Idem, May 31, 1919.

The union in the South did not break before a final struggle centering in and around Charlotte, N. C., where the union had retained a considerable membership. With the advent of the business depression in 1920, the mills began to reduce wages. By the spring of 1921, daily wages had been cut between 30 and 50 percent and the mills were running part time. The national officials of the United Textile Workers were extremely reluctant to sanction a strike, as requested by the North Carolina locals. Business conditions made a successful outcome doubtful; moreover, union funds were so low as to preclude the payment of strike benefits. However, a conference of representatives of 40 North Carolina locals was held at Concord on April 30, 1921. At this conference, the United Textile Workers agreed to lead the strike, and the representatives of the local unions agreed to waive their right to strike benefits. The national union promised such financial assistance as its funds would permit.[34]

About 9,000 workers answered the strike call on June 1, 1921. Mills in Charlotte, Rock Hill, Huntersville, Concord, and Kannapolis were affected. The mills were under no pressure to reopen. After the strike had continued for some weeks, an antiunion publicity campaign was inaugurated. For over 2 months, however, the strikers stood firm. Then the Governor dispatched troops to Concord and Kannapolis to restrain picketing, although no violence had occurred. The workers drifted back to the struck mills. By the end of August the strike was completely over. The workers went back under the wage rates prevailing when the strike was called. The union lost most of its membership. Thus ended the war and postwar boom period of textile unionism in the South.

COAL MINING, STEEL, AND OTHER INDUSTRIES

The World War I period provided a fresh opportunity for the United Mine Workers in the Alabama coal fields. In 1917, the union reentered the district. After building an appreciable membership, the union secured wage increases through strike action. Union recognition was not obtained.

Alabama miners participated in the national coal strike that began on November 1, 1919. A commission, appointed by President Wilson to study the situation and make an award, granted an increase in wages and urged the Alabama operators to "arrange to meet with representatives of the miners and put into effect the award." Apparently, most of the operators were willing to grant the wage increase, but they were not willing to establish contractual relations with the union. The United Mine Workers, however, insisted upon the creation of joint machinery for the settlement of disputes. The national officers of the union ordered a State-wide strike for September 7, 1920.

---

[34] Mitchell, op. cit. (pp. 51–52).

About 12,000 of the 27,000 coal miners in Alabama at that time walked out. About three-fourths of the strikers were Negroes. There was a good deal of disorder, and the National Guard was sent into the fields shortly after the dispute began. "The Alabama scene," according to Spero and Harris, "was as primitive and brutal as any of the earlier coal tragedies in which white men had been the sole participants." [35]

After 5 months, the strike began to weaken, although most of the men still held out. At this point, the union and the operators agreed to arbitrate the issues in dispute: (1) union recognition; (2) abolition of subcontract system; (3) reemployment of strikers; (4) readjustment of the day wage rate; (5) machinery for the settlement of disputes. The Governor of Alabama, who served as sole arbitrator, ruled against the union on every point. He held that the operators were under no obligation to reemploy striking miners. This award spelled temporarily the end of organization among the Alabama coal miners. After having spent 3 million dollars in Alabama, the United Mine Workers found itself with only a handful of determined unionists retaining membership cards.

Unionism also appeared during this period in the Alabama iron and steel industry. Unions of skilled craftsmen—machinists, sheet-metal workers, electricians, and others—entered the steel mills and metal working shops of the Birmingham district, and obtained a substantial membership. The International Union of Mine, Mill, and Smelter Workers organized the ore mines and also enrolled those workers in the mills who were not included in the various metal-trades unions.

When the companies refused the 8-hour day and other demands put forward by the workers, a general metal-trades strike was called. The strike was not successful. As a result of this defeat, Birmingham took little part in the great steel strike of 1919.[36]

In 1919, two American Federation of Labor unions—the International Timber Workers Union and the United Brotherhood of Carpenters and Joiners—recruited members among southern logging and sawmill workers. Union activity centered in Bogalusa, La., which was then among the largest lumber centers in the world. The Timber Workers were active at other points as well. Company opposition was bitter, and union members, both white and Negro, were subject to discrimination. A vigilante group was formed by the anti-union forces. On November 22, 1919, this group entered the union office in Bogalusa, killing Lum Williams of Mississippi, leader of the lumber workers in the Bogalusa area, and two other union men.[37] The episode effectively ended organizing efforts in the lumber industry in the South at that time.

---

[35] Spero and Harris, op. cit. (p. 361).
[36] Idem (pp. 247-249).

Clearly, a fairly extensive labor movement existed in the South during the World War I period. By 1922 or earlier, however, unionism had been liquidated in many of the industries in which substantial strength had been built up during the preceding 6 or 7 years. Cotton textiles, tobacco, iron and steel, and coal mining could muster, at best, a mere handful of union members, and unionism as a positive force had ceased to be of any importance in these industries. A measure of organization which had been built up in the petroleum industry in Texas had evaporated. Furniture and lumber had scarcely been touched by the wartime development. The southern labor movement by 1922 was again composed overwhelmingly of locals of skilled workers, although a residue of influence of factory unionism remained.

Upsurge in Textiles, 1922–29

Union activity in the southern textile industry did not entirely cease after the collapse of the movement in 1921. In a number of places in the South, local labor people managed to keep the spark of unionism alive in the cotton industry. Some help was obtained from the American Federation of Hosiery Workers.[38] This union became concerned about 1925 with the development of the full-fashioned hosiery industry in the South.[39] After that year, "the union has kept organizers in the South continuously, meeting the industry as it expanded in that section. It has not been content with sending organizers from the North, but has developed a southern leadership which now [1938] makes up the great majority of the southern organizing staff of the Federation." [40]

The textile industry in the South, in contrast with the New England industry, was relatively prosperous during the years following 1922. Union activity reappeared on a small scale in North Carolina. Textile locals were reorganized in Charlotte, Salisbury, and a number of other towns during 1922 and 1923. Several small strikes occurred in the Charlotte area and in the spring of 1923 many mills raised wages 10 percent or more.[41] In the fall of 1924 the workers in a Lexington, N. C., mill conducted a successful 1-week strike against a wage reduction.[42] Some gains were made through a strike of unorganized workers in the spring of 1925 at a cotton mill in Wilmington, N. C.[43] There were several other small strikes in North Carolina in 1925 and 1926.

---

[37] Jensen, op. cit. (pp. 91–94).

[38] Prior to 1933, when it assumed jurisdiction over seamless hosiery workers, this union was known as the American Federation of Full-Fashioned Hosiery Workers.

[39] George W. Taylor: The Full-Fashioned Hosiery Worker (Philadelphia, University of Pennsylvania Press, 1931), p. 83.

[40] Laurence Rogin: Making History in Hosiery (Philadelphia, American Federation of Hosiery Workers, 1938), p. 15.

An important dispute began on August 4, 1927, when the unorganized employees of a cotton mill in Henderson, N. C., walked out. These workers were attempting to obtain restoration of a wage cut made in 1924; they complained also about the condition of the mill houses and other matters. The strikers were aided by an organizer for the hosiery workers, and aroused the interest of officials of the State Federation of Labor. The walk-out lasted for about a month. Under threat of eviction from company houses, the workers returned to their jobs.[44] The dispute revived the whole question of textile unionism in the Upper Piedmont, and led to the formation late in 1927 of the Piedmont Organizing Council under the leadership of Alfred Hoffman of the hosiery workers. This group, in cooperation with local unions and city central bodies, conducted general union propaganda. Southern delegates to the 1928 convention of the American Federation of Labor laid plans for a union drive. Thus, toward the end of the decade, signs pointed to an expansion of union activity.

In the meantime, a new grievance had developed. In New England, industrial rationalization was being utilized in an effort to arrest the decline in cotton manufacturing in that area.[45] Southern mill management could not be indifferent to this new development. Consequently, the installation of efficiency systems in the South became widespread. The new production methods frequently were introduced quite abruptly, often without adequate technical preparation. Little effort was made to enlist the cooperation of the mill workers. The operatives themselves called the new techniques the "stretch-out" and added another grievance to the list that included low wages and long hours. The "stretch-out" was a contributing factor of considerable importance in the series of explosive strikes in 1929.

In 1929 cotton-mill strikes occurred in Gastonia and Marion, N. C., and at a number of places in South Carolina—Ware Shoals, Greenville, Woodruff, Central, Anderson, and Union. In addition, a bitter dispute in the rayon industry took place at Elizabethton, Tenn.

[43] Idem, April 1925 (pp. 268–269).

[44] News and Observer (Raleigh, N. C.), August 11–September 10, 1927; Mitchell, op. cit. (pp. 61–62).

[45] During the 1920's, the cotton manufacturing industry in New England was cut down by bankruptcy and voluntary liquidation. On the other hand, well over a million spindles, with a proportionate amount of complementary machinery, were added to southern equipment between 1923 and 1929. During the latter year, southern mills accounted for 76.3 percent of total cotton consumption in the United States.

These stoppages cannot be described in detail, owing to space limitations, but their chief characteristics should be briefly noted.

The Loray mill in Gastonia, N. C., was selected by the National Textile Workers' Union, a Communist-controlled organization affiliated with the Trade Union Unity League,[46] as the first objective in a drive for southern membership. Organization work began in January 1929. In this mill, an intensive drive to lower production costs had begun in 1927, with the result that "although expenses decreased and production mounted, to the great satisfaction of the board of directors, the operatives reacted violently against the new system and the man who inaugurated it."[47] Worker discontent became so great that the company in late 1928 replaced its resident manager and promised to lessen the intensity of the efficiency program.

The National Textile Workers' Union apparently was able to recruit membership rapidly in this situation. On March 25, 1929, five active unionists were discharged. The strike began on April 1, when approximately 1,800 of the 2,000 workers left the mill. The strike did not last effectively for much more than 2 weeks. After the first few days, the workers began to drift back to the mill, although the mill remained somewhat handicapped in its operations until the latter part of May.

The economic demands of the strikers received no consideration.[48] The political beliefs of the strike leadership were made the central issue and the State militia was sent into the community. Strikers were roughly handled, union headquarters were wrecked, workers were evicted from company-owned houses, and the dispute ended in a paroxysm of violence.

In Marion, N. C., another bitter dispute occurred, under the leadership of the United Textile Workers of the American Federation of Labor.[49] The strike began on July 11, when 650 operatives of the East Marion Manufacturing Co. walked out. For a time, the workers of the nearby Clinchfield Manufacturing Co. were also involved. This strike was related directly to the "stretch-out." When the superintendent of the East Marion mill added 20 minutes to the 10-hour work-shift to recoup installation losses for which the management was responsible, a committee of operatives sought union assistance. As in Gastonia, the strike was called when the mill began discharging active unionists. A month later, workers at the two Clinchfield mills were locked out. The lock-out was converted into a strike.

---

[46] The Trade Union Unity League and the unions affiliated with it were later disbanded after a change in Communist Party lines on trade-union tactics.

[47] Robin Hood: The Loray Mill Strike (unpublished M. A. thesis, University of North Carolina, 1932, p. 25). This thesis contains perhaps the best account of the Gastonia strike. See also B. U. Ratchford: Economic Aspects of the Gastonia Situation (in Social Forces, March 1930); Tom Tippett: When Southern Labor Stirs (New York, Jonathan Cape and Harrison Smith, 1931), chapter 6; and Mitchell, op. cit. (pp. 70–75).

[48] The union demands included (1) a minimum wage of $20 per week, (2) the 40-hour week, (3) better working conditions, (4) the addition of screens and bathrooms to the company houses, and (5) union recognition.

[49] See Tippett, op. cit., chapters 7–8.

The strike lasted for 3 months. It was called off after troops had stopped all forms of union activity and after a conference had been arranged to work out a settlement. A "gentlemen's agreement" was reached at the conference for (1) a trial reduction in the length of the workweek (to 55 hours); (2) the reemployment of all but a few of the strikers; and (3) the election of worker committees to deal with management. The reemployment provisions of this agreement were not kept. The situation was particularly bad at the East Marion plant. On October 1, the night shift walked out. When the day shift appeared, armed deputies inside the mill released tear gas and fired at the workers. Six strikers were killed and 30 wounded. Seven deputies were tried for murder; all were acquitted; four union men, on the basis of an earlier minor incident, were subsequently convicted of rioting. This ended the union effort at Marion.[50]

The 1929 stoppages in South Carolina were largely spontaneous and in some instances the workers indicated that they did not desire union participation. About 1,200 workers quit successfully at Ware Shoals in March in protest against a recently installed efficiency system. A short strike at Pelzer was settled at a conference of the strike committee and the mill management. A long dispute in four plants of the same company in Greenville and Woodruff ended without substantial gain for the workers. A 1-day strike against the "stretch-out" was settled favorably at Central. Other strikes occurred at Anderson and Union.

There were no union organizers on the scene on March 12, 1929, when 5,000 employees of the Bemberg-Glanzstoff rayon companies in the mountain town of Elizabethton, Tenn., began their walk-out. Not until the dispute got under way were requests for organizers sent to the American Federation of Labor. Low wages, long hours,[51] and the stretch-out were among the causes of discontent. The strikers demanded a 25-percent wage increase and union recognition. Injunctions were issued against the strikers and troops were sent in.

The strike ended after 11 days. The companies agreed to equalize the wages of men in the two plants, to raise the wages of women by about 20 percent, and to meet with employee committees over grievances. The union was not recognized.

Shortly after the end of the strike, many active unionists were discharged. On April 3, two union men, including the personal representative of President Green of the American Federation of Labor, were kidnapped in Elizabethton and carried from the State. They returned several days later accompanied by President Green. A mass discharge of unionists occurred on April 15 and 4,000 workers walked out in a second strike. Again troops were brought in and a considerable amount of violence developed. The union's funds were not adequate for the relief problem created by the strike. The strikers began drifting back to work and on May 25 a settlement was negotiated. This settlement again did not include union recognition.

---

[50] As a result of the strike, hours were reduced. A sewer system and plumbing were installed in the East Marion village. The Clinchfield mills granted a small wage increase.

[51] Average weekly wages were about $15 for males and $10 to $11 for females for a 56-hour week.

After the strike, a company union was installed and an elaborate company welfare program inaugurated. The United Textile Workers tried unsuccessfully to hold its membership. An abortive strike took place in March 1930, marking the final collapse of the union in Elizabethton.

The 1930 Organizing Campaign

Tremendous enthusiasm for a southern organizing campaign was displayed at the 1929 convention of the American Federation of Labor.[52] The executive council of the Federation reported: "These workers in the South are poor and they have suffered much by the recent strikes. It will take time to develop self-supporting unions. Responsibility for establishing higher wages and better conditions of employment must rest with the national and international unions." [53] A resolution for an organizing campaign introduced by the United Textile Workers was adopted.

The drive got under way on January 6, 1930, at a large conference in Charlotte, N. C. Among those at the conference were 229 delegates from southern unions, organizers from 26 national unions and the Federation, delegates from seven State federations and from a number of city central bodies, and local workers from 95 different crafts. It was decided to establish headquarters at Birmingham, and a coordinating committee of three was selected. At the height of the drive, more than 50 organizers were in the field.[54]

Part of the initial strategy of the campaign was to convince employers of the advantages of trade-unionism. During the years of relative economic stability following 1922, the labor movement had become increasingly interested in union-management cooperation and in production problems. The United Textile Workers itself had participated in a union-management cooperation effort since 1924 in the Naumkeag Steam Cotton Mills at Salem, Mass.[55]

[52] A F. of L. Proceedings, 1929 (pp. 225–283).

[53] Idem (p. 60).

[54] Idem, 1930 (pp. 85–86).

[55] See Richmond C. Nyman and Elliott Dunlap Smith: Union-Management Cooperation in the "Stretch-Out" (New Haven, Yale University Press, 1934) for a detailed account of the Naumkeag experiment.

At least at this time the union-management cooperation idea failed to appeal to either employers or workers in the South.[56] Therefore, a more militant approach was adopted. Two factors served as barriers to success. The first was the general business depression beginning in the fall of 1929. In the second place, the union resources available for the campaign were not large. Despite these obstacles, 112 new local unions had been organized in the South by September 1930; 81 of these locals were in industries other than textiles.[57] The 31 new locals of the United Textile Workers were found in Virginia, North and South Carolina, Georgia, Alabama, and Tennessee.

The strength of cotton unionism was in the upper Piedmont. In North Carolina, the union signed up large numbers of workers at the Marshall Field mills in Leaksville-Spray and Draper, and at the great Cone mills in Greensboro. In Danville, Va., the union built up a substantial membership at the Riverside and Dan River Cotton Mills.

The test came at Danville, where the unqualified refusal of the company to deal with the union made a stoppage almost inevitable. For months, the mill refused to meet with union representatives; during the same period active union workers were being discharged. The national convention of the United Textile Workers authorized a strike and 95 percent of the union members in Danville voted for a walk-out. The strike of 4,000 workers began on September 29, 1930.

The strike had substantial support from the community at large. All offers of mediation were refused by the company. Injunctions restrained effective picketing. Strikebreakers were imported. Minor acts of violence occurred and State troops were sent in. Eviction notices were issued. The relief problem faced by the union increased in seriousness as the months passed.

The strike was broken after 5 months. The Danville defeat marked the end of the southern organizing campaign.[58] Textile-union membership elsewhere in the South melted away, although the United Textile Workers retained a small following in the region.[59] The deepening economic depression provided poor soil for new union growth.

Labor Unrest in Depression

The depression did provide the occasion for two instances of largely unorganized labor revolt in the South. During the summer and fall of 1932, a series of strikes swept over North Carolina.[60] The ranks of the strikers were composed of seamless-hosiery workers, full-fashioned hosiery workers, silk workers, cotton-mill operatives, and furniture workers.

[57] A. F. of L. Proceedings, 1930 (p. 86).

[58] See Tippett, op. cit., chapter 10; Herbert J. Lahne: The Cotton Mill Worker (New York, Farrar & Rinehart, 1944, pp. 221-224.)

[59] See reports in the Textile Worker, 1932.

On July 18, 1932, a few hundred stocking boarders walked out of six hosiery mills at High Point, N. C. The walk-out was in protest against a drastic wage reduction, the second of the year. The movement spread until 24 hosiery mills employing 5,000 seamless-hosiery workers were closed.[61] After 10 days, the dispute was settled by the restoration of the wage cut and certain other concessions.

On August 23, workers in three cotton mills in Rockingham walked out. The demands included restoration of two wage cuts made during the year, the 10-hour day, and a reduction in the rent of company-owned houses. Railroad union locals in Spencer and Hamlet, textile workers in Salisbury, and farmers from the surrounding countryside provided food for the strikers. The stoppage lasted for almost 2 months. None of the strikers' objectives were gained except the reinstatement of all employees. Other North Carolina strikes during this period involved 600 full-fashioned hosiery workers in High Point, about the same number of cotton-mill workers in a mill village near High Point, 500 employees of a silk works in High Point, and a thousand furniture workers in Thomasville.

Walk-outs during 1932 were largely spontaneous. The seamless-hosiery workers in High Point formed an independent union during their strike; this unaffiliated union had a checkered career for several years and then expired. In Rockingham, an independent union was formed just prior to the strike and collapsed when the walk-out failed. Some workers in High Point joined the American Federation of Full-Fashioned Hosiery Workers and the American Federation of Silk Workers.

In the Kentucky coal country, where unionism had never developed, revolt also flared over the conditions produced by wage cuts and part-time work during the depression. Discharges for union activity accompanied the beginnings of unionization. In April 1931, 18,000 miners walked out under the leadership of the United Mine Workers. After a gun battle between miners and deputies at Evarts, the militia was sent into Harlan County. The leadership of the strike shifted to the Industrial Workers of the World. The strike was broken. An attempt by the Communist National Miners' Union to call a strike in neighboring Bell County on January 1, 1932, failed.

---

[60] For a detailed account of these stoppages see H. M. Douty: Labor Unrest in North Carolina, 1932 (in Social Forces, May 1933).

[61] Owing mainly to the action of roving bands of unemployed workers, over 150 industrial plants in and around High Point were closed for a few days.

The NRA Period

These labor disputes, and others of lesser significance, revealed the existence of deep unrest. With the passage in 1933 of the National Industrial Recovery Act, which guaranteed to labor in section 7 (a), the right to bargain collectively through representatives of its own choosing, large numbers of workers in the South and elsewhere crowded into unions. As it turned out, the labor provisions of the Recovery Act were not highly effective because of the lack of adequate enforcement machinery. However, the collective-bargaining clause of the act, together with a measure of industrial recovery, unquestionably gave rise to a great upsurge of union activity.

Some unions were more active during the NRA period than others. The United Mine Workers, for example, sent a corps of organizers into the coal country. The third major attempt to organize the Alabama field began in the summer of 1933. By 1935 the union had more than 23,000 members in Alabama, more than half of whom were colored. On May 26, 1937, the United Mine Workers signed contracts with every mine in the State.[62] The miners' union also obtained a large membership in Tennessee. In August 1938, the Harlan County Coal Operators' Association signed the standard Appalachian agreement, thus ending an era in the history of "bloody Harlan." [63]

The tobacco workers' union extended its influence during this period. As early as November 1933, the union reported that 90 percent of the white workers in the cigarette department of the American Tobacco Co. in Durham, N. C., had joined the organization.[64] By the summer of 1934, the white employees of Liggett and Myers in Durham had also organized, and there was union membership in Reidsville and Winston-Salem. The union also established locals in Virginia. Negro tobacco workers were drawn into the movement, but were not at this time effectively integrated into the union. By the end of the NRA period, the union had a contract with the Brown and Williamson Tobacco Co. and with a number of smaller firms,[65] and apparently exerted some influence on the major companies.

Although some unionism developed in the southern iron and steel industry during the NRA period, the movement was not strong enough to exert much influence on labor relations. Some union locals were formed among Alabama ore miners. The petroleum industry in the Southwest was penetrated for the first time since the World

[63] Idem, October 1938.

[64] Union Herald (Raleigh, N. C.), November 2, 1933.

[65] Herbert R. Northrup: The Tobacco Workers International Union (Quarterly Journal of Economics, August 1942). This article contains an excellent account of the development of the union, including an analysis of the internal struggle that resulted in a change in national leadership in 1939.

War I period. Union activity in the southern lumber and furniture industries was meager. On the other hand, many of the workers in the semiskilled and skilled trades were organized in most of the southern cities, some for the first time. Many city central bodies were revived, some new ones organized, and functioning city centrals greatly strengthened.

The most spectacular development in southern unionism during the NRA period occurred in cotton textiles. The United Textile Workers quickly gained a substantial membership in cotton mills throughout the region; the hosiery workers' union also was active. Discharges for union activity and other violations of the labor provisions of the NRA were numerous. The "stretch-out" problem was intensified by the efforts of mill managements to cut costs in face of the minimum-wage and maximum-hour provisions of the cotton-textile code. Scattered local strikes did not prove effective in improving conditions in the industry. At the union convention in August 1934, delegates from the South joined with delegates from New England in calling for a general strike. The convention fixed September 1 as the date for the stoppage.

Unsuccessful efforts were made to forestall the strike. On September 1, about 100,000 cotton operatives in the South walked out. At its peak, the workers on strike in the South numbered about 170,000.[66] Shortly after the beginning of the strike, President Roosevelt appointed a board of inquiry. This board recommended: (1) that a new textile labor relations board be appointed; (2) that the Federal Trade Commission investigate the ability of the industry to support a higher wage structure; (3) that the cotton, wool, and silk codes be amended to permit the functioning of a special committee to regulate the "stretch-out"; (4) that a study be made by the U. S. Department of Labor of occupational wage rates in the industry.

On the basis of these recommendations, the United Textile Workers called off the strike on September 22. Subsequently, President Roosevelt appointed a textile labor relations board to investigate alleged violations of section 7 (a) of the NRA, to arbitrate questions voluntarily submitted, and to exercise such functions as might be granted by code provision. This board appointed a special committee to investigate the subject of the "stretch-out." The Bureau of Labor Statistics initiated a survey of hours and earnings in the principal textile industries and the Federal Trade Commission began a survey of the financial condition of textile enterprises.

---

[66] The vast majority of those on strike in the South were cotton-textile workers. The strike was extended to the wool and worsted, silk, hosiery, and miscellaneous textile industries, but these industries (except hosiery) were very thinly represented in the South.

This greatest of all textile strikes brought few tangible or immediate gains to the workers. The companies did not recognize the union, wages remained unchanged, and, as it turned out, the new textile board was no more effective than the old in protecting the right of workers to organize and bargain collectively. The use of the "stretch out" was apparently tempered. The workers themselves interpreted the result as a defeat. Many were refused employment at the end of the strike, and union membership declined sharply during the months that followed.

The textile strike marked the high tide of unionism in the South during the NRA period. Loss of the strike had unfavorable repercussions upon union organization in other industries. In textiles, however, the union retained part of its membership, and gains in other industries by no means disappeared. When the NRA (in May 1935) was declared unconstitutional, the labor movement in the South was considerably stronger than it had been 2 years earlier.[67]

National Labor Relations Act, Union Rivalry, and War Years 1935–45 [68]

Two developments in 1935 were to have great significance for the labor movement in the South and elsewhere.

Less than 2 months after the invalidation of NRA, the National Labor Relations Act became law. One of the purposes of this act was to continue and strengthen the collective-bargaining provisions of section 7 (a) of the National Recovery Act. The act asserted that employees in industries under its jurisdiction had the right to self-organization, and employers were forbidden to engage in certain "unfair labor practices" that tended to discourage union membership. The act also placed upon employers the duty to bargain collectively with representatives freely chosen by their employees. The effective administration of the act was initially hampered by the question of constitutionality; this question was resolved in April 1937.[69]

Shortly after the 1935 convention of the American Federation of Labor, a group of union leaders formed the Committee for Industrial Organization (CIO). This action represented almost the last stage in a long conflict within the Federation over the appropriate form of union organization for the mass-production industries. Involved were the jurisdictional claims of the craft unions in the steel, automotive, rubber, and similar industries. A substantial minority opinion within the Federation held that such industries could only be effectively organized on an industrial basis.

---

[67] Labor organization in southern agriculture is not covered in this article. It should be noted, however, that the Southern Tenant Farmers Union (now the National Farm Labor Union affiliated with the American Federation of Labor) was formed in 1934. For an exhaustive account of farm labor unionism in the South see Bureau of Labor Statistics Bulletin No. 836, Labor Unionism in American Agriculture (pp. 256–355).

[68] The writer is indebted to the Union and Management Research Division of the Bureau's Industrial Relations Branch for assistance with this section.

S. 58; *Washington, Virginia & Maryland Coach Co.* v. *National Labor Relations Board*, 301 U. S. 142.

Almost immediately after the organization of the Committee, requests for organizing assistance began to pour in from workers in many industries, and the Committee was soon carrying on a tremendous organizing campaign. In 1938, the Committee became the Congress of Industrial Organizations, thus creating a rival to the existing labor federation.[70]

In terms of the southern labor movement, the most outstanding action of the CIO was the creation, in March 1937, of the Textile Workers Organizing Committee in agreement with the United Textile Workers.[71] In the organizing campaign that followed, the TWOC proceeded cautiously, utilizing fully the procedures of the National Labor Relations Act. Strikes were avoided wherever possible. A recession in business activity, beginning in the fall of 1937 and lasting into 1938, tended to slow the drive.

As of May 31, 1941, the Textile Workers Union (CIO), which had grown out of the Organizing Committee,[72] had won National Labor Relations Board representation elections in 46 southern cotton mills employing over 32,000 workers; in addition, the union had been certified without elections as collective-bargaining agent in five southern mills. In these 51 mills, however, the union had been able to secure actual collective-bargaining agreements in only 29. As of May 31, 1941, the union had 23 collective agreements covering over 17,000 workers with southern cotton mills.[73]

After 1941, the union advance continued slowly. Contracts were signed with a number of the larger mills, including the Erwin Cotton Mills and the Kendall Mills. An important election, and subsequently an agreement, was won at the Riverside and Dan River Cotton Mills.[74] The tempo of the union's activity in the South during 1943–46 can be gaged from the report of its executive council to the fourth biennial convention: "The union's organizational progress in the South continued slowly but certainly. . From Virginia to Alabama we picked up mill after mill during the 3 years, all but a few of them cotton mills. TWUA also invaded Texas for the first time, winning elections in 11 mills in the eastern part of the State. . . . In point of numbers, workers organized during the 3 years in the South were principally concentrated in North Carolina and Georgia." [75] It was stated that 20 percent of the southern cotton and rayon workers were represented by the Textile Workers Union.[76]

---

[70] An excellent brief account of the formation of the CIO may be found in Harry A. Millis and Royal E. Montgomery: The Economics of Labor: Organized Labor (New York, McGraw-Hill Book Co., 1945), III (pp. 201–242).

[71] In 1939, a group of locals of the United Textile Workers was reinvested with the charter of that organization by the American Federation of Labor. In the same year the Textile Workers Organization Committee and the majority group in the United Textile Workers united to form the Textile Workers Union of America (CIO). Thus, at the present time both the AFL and the CIO have unions competing for membership in the textile industry. See Herbert J. Lahne: The Cotton Mill Worker (New York, Farrar & Rinehart, 1944), pp. 262–269, 273–277.

[72] See preceding footnote.

[73] Lahne, op. cit. (pp. 270–271).

[74] Textile Workers Union of America, Third Biennial Convention, 1943, Proceedings (pp. 121–122).

Meantime, the United Textile Workers (AFL), which was reconstituted in 1939, also made some progress in the South. By September 30, 1942, the UTW had won bargaining rights in nine southern cotton mills employing almost 6,000 workers [77] and additional gains were made later.[78] Membership in the United Textile Workers nationally has increased rapidly from a very small number in 1939.[79] The bulk of the membership in both AFL and CIO unions at present is in branches of the industry other than cotton.

With respect to the South, the existing situation is different from any existing in the past. Cotton unionism is functioning in the South; a number of mills, including some very large units, are under contract.[80] Nationally, textile unionism has never been stronger. However, the bulk of the industry in the South remains unorganized.

As previously stated, the Tobacco Workers International Union (AFL) concluded collective-bargaining agreements with a number of companies in the industry during the NRA period. In 1937, after the validation of the National Labor Relations Act by the Supreme Court, the union negotiated agreements with Liggett and Myers, American Tobacco Co., and Philip Morris covering workers in their North Carolina and Virginia plants. In 1940, after a hard fight, agreements were signed with P. Lorillard Co. for employees in Louisville, Ky., and in New Jersey.[81] The Food, Tobacco, Agricultural and Allied Workers Union (CIO) has some membership in the industry, notably at the large Winston-Salem, N. C., plant of the R. J. Reynolds Tobacco Co.

[76] Idem (p. 49).

[77] Lahne, op. cit. (p. 275).

[78] See the Textile Challenger, official organ of the union.

[79] When rechartered in 1939 by the American Federation of Labor, membership in the United Textile Workers was only 1,500. See Anthony Valente: Let's Talk About Textiles (in American Federationist, April 1946, pp. 16–17).

[80] For an analysis of union agreements in cotton manufacturing in 1945, see Rose Theodore: Union Agreements in the Cotton Textile Industry (in Monthly Labor Review, March 1946, pp. 413–423).

[81] John O'Hare: The Tobacco Worker (in American Federationist, June 1946, p. 22). See also Herbert R. Northup: Tobacco Workers International Union (in Quarterly Journal of Economics, August 1942, pp. 615–616).

By the close of 1944, approximately 90 percent of the workers in the industry (cigarettes, chewing and smoking tobacco, and snuff) were employed in plants which had trade-union agreements. Agreements negotiated by the Tobacco Workers International Union covered almost three-fourths of the organized workers. In the cigar industry, about half the workers were organized in 1944. The Cigar Makers' International Union (AFL) had its major strength in the Florida area; most of the cigar workers under agreement with the Food, Tobacco, Agricultural and Allied Workers (CIO) were employed outside the region.[82]

Possibly the most dramatic of all the CIO organizing campaigns—in the steel industry[83]— started in 1936. In March 1937, a formal agreement was signed between the Steel Workers Organizing Committee and various subsidiaries of the United States Steel Corp., including the Tennessee Coal, Iron and Railroad Co. in Birmingham. By this agreement the union was recognized as the collective-bargaining agent only for those employees who were its members. In Birmingham, about 5 years elapsed before the union, in a series of representation elections under the National Labor Relations Act, obtained sole bargaining rights. By 1943, however, steel unionism was well established in Birmingham. In addition to Tennessee Coal and Iron, the union (now the United Steel Workers) has won bargaining rights in other iron and steel plants in Alabama and in metal fabricating plants, as well. Iron-ore miners in the Birmingham area are represented by the International Union of Mine, Mill and Smelter Workers (CIO).

The union situation in other industries is briefly noted. A very substantial organization has been built up in the southern pulp and paper industry by the Pulp, Sulphite and Paper Mill Workers (AFL). Most employees of the Tennessee Valley Authority work under agreements negotiated with the Authority by various unions affiliated with the AFL.[84] In 1944, the United Rubber Workers (CIO) had 11 agreements and 9 locals in the South.[85] The locals were situated in Alabama, Georgia, Tennessee, Virginia, North Carolina, and Kentucky. By 1942, the Oil Workers International Union (CIO) had 28 working agreements in the petroleum industry in Louisiana and Texas.[86] In 1943, the organizing work of the union was revitalized, and material progress was reported at subsequent conventions. It is now (1946) estimated that over 60 percent of the workers in the refining branch of the industry are working under the terms of collective bargaining agreements, largely with the Oil Workers International Union.

[86] Oil Workers' International Union, Reports of the Executive Council, Thirteenth Convention, 1942 (pp. 16–17).

The National Federation of Telephone Workers (independent) had more than 13,000 members in 1944 in its Southern Federation of Telephone Workers (covering the territory of Southern Bell in 9 Southeastern States, including Louisiana).[87] The union also had members in Texas. For a decade, the Amalgamated Clothing Workers (CIO) has conducted active organizational work in the men's clothing industry, primarily cotton garments, in the South, and has built up an appreciable membership. The United Garment Workers (AFL) also has membership in the region. The International Ladies Garment Workers Union (AFL) reported more than 11,000 members in some 60 locals in its Southwestern District in 1944.[88] Apparently, this district covers part of Illinois and Missouri, in addition to Texas, Arkansas, and Tennessee. Locals of the union are also found at Atlanta, Knoxville, and elsewhere in the Southeast. As of 1944, the United Automobile Workers (CIO) had 31 plants under contract in the South.[89] Most of these plants were engaged in turning out war materials, including aircraft. The enormous expansion of the southern shipbuilding industry during the war was accompanied by extensive organization, by both AFL and CIO affiliates. Longshore organization also increased.

It is clear that union organization in the South is substantial in character and is no longer restricted to its traditional spheres in railroading, printing, and a few other industries. Much of the present organization, of course, has developed during very recent years, and its stability, in many cases, has yet to be tested. The existing position has been reached, as this article in very summary terms has attempted to show, after a comparatively long period marked by many sacrifices on the part of labor and in spite of bitter defeats. The persistence of the efforts of workers in the South to organize reflects the importance attached by workers to the role that trade-unionism can play in modern industrial society.

Even during World War II years, the great lumber industry in the South remained virtually untouched by union organization. The bulk of the southern textile industry is unorganized. In the furniture and chemical industries unionism is weak. Food-processing has been largely untouched, together with a great variety of service trades and many miscellaneous manufacturing industries.

Organizing Campaign of 1946

A new chapter in the history of southern trade-unionism began in the spring of 1946, when both the CIO and the AFL announced plans for major organizing campaigns in the South.[90] Both organizations reported progress by late summer, but no appraisal is yet possible of the results of these efforts to extend labor organization in the region.

Some Factors in Southern Unionism

Historically, unionism in the South has reflected the strength and weakness of organized labor in the country as a whole. The relative size of the southern movement, its scope, and its structure have been determined, in part, by the size, scope, and structure of the labor movement nationally. In 1929, for example, southern organization was comparatively meager. In that year, however, only 10.9 percent of the employed wage earners in manufacturing in the country as a whole were organized, and this figure includes the railroad shop crafts.[91] Moreover, 71.5 percent of all trade-union members in 1929 were in five industry groups—mining, building, transportation, clothing, and paper and printing.[92]

Unquestionably unionism in the South has had—and to some extent still has—greater obstacles to overcome than unionism in most other parts of the country. The retarding factors listed below, however, are not to be regarded as characteristic exclusively of the South. They exist in some measure elsewhere in the Nation.

(1) Industrialism on a substantial scale in the South is comparatively recent. Many of those who now compose the industrial working force have come direct from farms; many others are only one generation removed from the land. Strong unionism requires sustained collective action, and the habits and attitudes that promote such action grow in part out of the discipline that industry itself imposes. As urban-industrial behavior patterns more and more supplant agrarian behavior patterns among southern workers, cohesive unionization may more easily be achieved.

(2) Many groups of southern workers occupy an exposed position and are difficult to organize because of the pressure on industrial-job

---

[90] A convenient statement of CIO objectives may be found in the May 1946 issue of its Economic Outlook. The AFL drive was opened at a large conference in Asheville, N. C., in May 1946. See Report, Third Biennial Southern Labor Conference.

[91] Leo Wolman: Ebb and Flow in Trade Unionism (New York, National Bureau of Economic Research. 1936), p. 123.

[92] Idem (p. 87).

opportunities of large numbers of desperately poor people from the agricultural areas. The labor market has rarely been firm in the South except in time of war. During the next decade or two, the competition for industrial jobs may increase depending upon (*a*) the rate at which agricultural labor is displaced because of technological and market factors; (*b*) the rate at which job opportunities in southern industry are created; (*c*) the rate at which migration out of the South takes place.[93]

(3) Historically, the company-owned town has been another obstacle to union advance. This factor has been highly important in the textile industries; it has been important also in coal mining and some other industries. The significance of the company-owned town as a barrier to unionism was reduced substantially with the passage of the National Labor Relations Act.

Another locational factor is the extent to which industry in the South is dispersed over a wide geographic area. Southern industry characteristically is located in small and medium-sized communities. As southern industry continues to develop, this locational pattern undoubtedly will tend to persist. There is much to be said in human terms for the avoidance of huge urban concentrations; the only point being made here is that the scattered nature of southern industry makes the process of union organization more difficult.

(4) The biracial character of the southern labor supply also presents problems in the growth of unionism. Race prejudice has been used to break strikes in the South (and elsewhere) and to keep workers divided along racial lines. There is membership discrimination against Negroes by some unions.

The Negro constitutes a relatively large and permanent part of the southern industrial labor force in such industries as tobacco, lumber, and iron and steel. Successful unionization of such industries will require the organization of colored workers. There is evidence to the effect that workers among both races are beginning to realize that economic cooperation is not only possible, but desirable. As this feeling grows, general racial understanding also tends to increase. Some unions—the United Mine Workers is an example—have done a magnificant job in cementing union bonds among members of the two races.

A number of factors tend to favor union growth: (1) That elusive but important factor, public opinion, is changing. Beginning about 1900, sentiment grew slowly in the South for various forms of labor legislation.[94] During the 1920's, some southern ministers, editors, and teachers began to voice publicly the belief that workers should have the right to join unions if they wished to. After 1929, the reexamination of attitudes on many social problems among large sections of the population accelerated the growth of general tolerance toward union organization. This change in public opinion is more pronounced in some parts of the South than in others. In general, opposition to unions tends to vary inversely with the degree of industrialization.

---

[93] See the section Labor Supply in the South, p. 16 of this bulletin.

[94] See the section State Labor Legislation in the South, p. 118 of this bulletin.

(2) The southern working class is becoming more mature, in the sense of having more confidence in itself as a group. The nature of unionism is better understood, owing partly to the accumulation of past experience with labor organization and to the growth of union organization during the past decade; partly to the persistence of a general union propaganda in the region coupled with the development of a more favorable public attitude; and partly to the fact that mere participation in industry affords lessons in collective action.

(3) Undoubtedly, a factor of great importance in the South (and elsewhere) is the existence of the National Labor Relations Act. For a long time workers in this country have had the unquestioned legal right to seek collective bargaining by legal means. But until the passage of the National Labor Relations Act in 1935, employers did not have placed upon them the reciprocal duty to enter into collective-bargaining relations. Moreover, through its definition of "unfair labor practices," the act deprived employers of powerful weapons they formerly were able to use to discourage unionization.

(4) A final favorable factor at present is the existence nationally of a stronger trade-union movement than at any time in our history and of greater organization within the South itself than at any previous time. The AFL alone has at least doubled its membership during the past decade, and the CIO has emerged as a powerful trade-union center. The structure of the labor movement has altered profoundly with the rise of industrial unions in the great mass-production industries. As a result, any general organizing campaign in the South is likely now to be better staffed and better financed, and to take advantage of more flexible organizational forms, than any of the earlier campaigns. The assistance that can be expected from those unions already firmly established in the region is also a consideration of material importance.

XII.—Cooperatives in the South[1]

With certain exceptions, the South[2] has shown comparatively little development in the field of consumers' cooperation. The exceptions are cooperative credit associations (credit unions), students' cooperatives, electricity associations formed under the Rural Electrification Administration program, farmers' associations dealing in petroleum products and home and farm supplies, and medical care. There are, of course, a great many farmers' cooperatives in the South which market their members' farm products or purchase farm supplies (producer goods) for them; such associations are not, however, dealt with in this review unless they also handle consumer goods.

At the end of 1945, the latest date for which information is available, the 13 Southern States under consideration had a total of 1,494 credit unions, or 17 percent of all such associations in the United States; they accounted for nearly 13 percent of the membership and 11 percent of the total credit union assets. Texas alone had 334 credit cooperatives, and Florida, Georgia, Kentucky, Louisiana, North Carolina, and Tennessee had over 100 each.

The great majority of these credit unions were urban associations with membership largely drawn from industrial and other employees. Considerable numbers of the student cooperatives were also in the cities and large towns. With the exception of these two groups and the relatively small number of urban or nonfarm stores and buying clubs, practically all of the development in these States is in rural areas, among the farmers. As far as the records of the Bureau of Labor Statistics show, in these States 4 cooperatives have been organized by labor unionists. These include two cooperative store associations started by members of a textile union in Alabama in 1936 and 1937, respectively, and two formed by union oil-field workers in Texas in 1946.

In the cooperative provision of medical and hospital care, the South has shown the way to the other sections of the country. This has been due to several circumstances: the need of a group of Cuban cigar makers in Florida for protection against the health hazards of their trade in a community in which they were alien in tongue and customs, which led to the formation of their own medical facilities many years ago; the efforts of a single physician to improve the health of his farmer patients, which resulted in the building of a cooperative hospital in Oklahoma; and the recent passage of a law in Texas authorizing cooperative hospitals in rural communities, which has led to the formation of a score of hospitals during the past year.

---

[1] Prepared by Florence E. Parker of the Bureau's Labor Economics Staff.

[2] The term "South" relates to Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia.

During the subsistence-homesteads program, many homesteads projects were established in the South. A common accompaniment was the formation of a cooperative association which marketed the members' produce or ran a store for supplying groceries and other household goods, or both. Altogether some 50 distributive cooperatives handling consumer goods were formed. As of January 1, 1947 the homesteaders had bought the store property from the Government in 21 cases and were continuing its operation cooperatively. In the remaining cases the cooperative association had been liquidated; in most instances the Government loan had been paid in full.

Development in Individual States

In addition to nearly 80 credit unions and about 20 electricity associations formed under the Rural Electrification Administration program, *Alabama* has a number of farmers' purchasing associations—one of these among sharecroppers—and several students' cooperatives (including 2 at Tuskegee Institute). Under the Farm Security Administration's subsistence-homesteads program, also, several purchasing associations and health cooperatives were formed among the homesteaders in this State. In 6 of these the homesteaders had bought the store, and were operating it cooperatively at the end of 1946 (one of these is a Negro association).

As *Arkansas* had an even larger part than Alabama in the FSA program, a considerable number of its cooperatives were those of subsistence homesteaders. Most of these cooperatives carried on the marketing of their members' produce in addition to their consumer activities. At the end of 1946, 6 of these (4 Negro) were still in operation. Of the 4 Negro associations, 2 were land-leasing associations which also purchased consumer goods. Both had been conspicuously successful in farming the land, so much so that in one case the owner refused to renew the lease except at a prohibitive price, so that the association has no future unless it can obtain other land; the lease of the other association still has several years to run. The other 6 FSA cooperatives in this State had either been liquidated or were in process of liquidation at the end of 1946. The State's other consumers' associations included several students' cooperatives and farmers' purchasing associations, 18 REA cooperatives providing electric power, and 25 credit unions.

Florida associations include 160 credit unions, 12 electricity cooperatives, and a small number of retail distributive associations.

This last group contained (in addition to several farmers' purchasing associations) 2 students' cooperatives (one of veterans), a store at a migratory workers' camp, and one of the oldest Negro cooperatives in the United States. Florida also has a number of associations, formed by cigar makers of Cuban descent, which provide medical and hospital care in their own clinics and hospitals; several of these date from the 1890's and early 1900's. One of the Florida credit unions is reported to have taken a step unusual for such organizations, by buying land on which it is planning to build some 400 houses. All of the subsistence-homesteads cooperatives had gone out of existence by the end of 1946.

Georgia has 132 credit unions and 44 electricity cooperatives, a unique association dealing only in religious films, and cooperatives in at least five institutions of higher education. Among its retail cooperatives are several formed by residents in low-cost housing projects, and one is in an entirely cooperative community. A good deal of organizing work is going on—especially among labor and veteran groups—which is expected to result in some new cooperatives during 1947.

The consumers' cooperatives in *Kentucky* consist mainly of credit unions (104 in number) and REA cooperatives (26). The few distributive associations are those on college-campuses (including two in settlement schools) and a few farmers' cooperatives handling petroleum products and/or farm and household supplies.

The consumers' cooperative movement in *Louisiana* includes several cold-storage associations, a few buying clubs and stores, 13 electricity associations, and 131 credit unions. None of the cooperatives at subsistence-homesteads projects was in operation at the end of 1946.

Cooperatives are few in *Mississippi*. Even the credit unions numbered only 26 in 1945—the lowest of the 13 States here considered. Electricity cooperatives totaled 23 in 1942. Other types include 2 cold-storage associations, one surviving homesteads cooperative (of 5) and a few stores; one of the latter is a students' cooperative at a Negro college.

Credit unions are numerous in *North Carolina* (195 in 1945); REA associations (30), students' associations (6), and farmers' purchasing cooperatives (12) have also had a moderate development. One of the farmers' associations is in a community where, with the assistance of a local "folk school," many activities have been organized on a cooperative basis. Perhaps the greatest relative achievement has been among the Negroes; their 3 associations, although not large, have been well supported and have rendered valuable service to their members. At least one of the farmers' purchasing groups and one of the Negro associations have a credit union in connection. Of 4 stores started in connection with FSA homesteads, 2 (1 Indian and 1 Negro) remain.

In *Oklahoma* nearly all the farmers' purchasing cooperatives handle petroleum products and many deal in groceries; these are, with credit unions, the outstanding types of cooperation, numbering 60 and 71 each. The State also has the one cooperative funeral association in the South, 2 cooperative hospitals, several campus cooperatives and cold-storage associations, and 23 electricity cooperatives.

South Carolina has had comparatively little cooperative development, the representation there consisting of 35 credit unions, 24 REA cooperatives, a few store associations (including one whose members are colored), and several students' associations (2 Negro). The same situation exists in *Tennessee* where, with the exception of 117 credit unions and 19 electricity associations, the consumers' cooperative development consists of several urban or nonfarm buying clubs and stores, one or two campus cooperatives, a few cold-storage associations, and a medical association in a cooperative community.

Among the 13 States here considered, *Texas* is easily preeminent as regards cooperatives. At the end of 1945 it had 334 credit unions, or over twice as many as any of the other 12 States, and 72 REA cooperatives. It also showed an extensive distributive development among the farmers. There were in the State some 50 petroleum associations, in addition to many farmers' marketing or purchasing associations which also dealt in petroleum products. It is the only Southern State with a cooperative wholesale of the federated type (i. e., in which the members are retail cooperatives). The wholesale, at Amarillo, has been operating since 1931, and until a few years ago dealt almost wholly in petroleum products. Within the past few years it had been adding new lines, has opened up two branch warehouses in order to serve its large territory better, and has expanded into production. It now owns an oil-compounding plant, a feed mill and grain elevator, and a petroleum refinery. It is affiliated with National Cooperatives, the central purchasing agency of the consumers' cooperative movement in this country. Under the guidance of the wholesale, the affiliated retail associations in Texas have been diversifying their activities; many now handle groceries and various other merchandise. Consumers' cooperation has only recently begun to take hold among nonfarm groups. The very few nonfarm cooperatives started thus far include two formed in 1946 by members of an oil-field workers' union.

As already noted, Texas now leads the United States in number of cooperative hospital associations. By June 1946 there were at least 20 of these. Although one of these associations was organized in 1940 and opened its hospital in 1942, the rest have been formed during the past year. This is the result of an act passed by the Texas Legislature in 1945, which authorized the formation of cooperative hospitals in places of 2,500 or less. Most of the associations thus far formed plan to extend their service over the entire county in which the headquarters is located.

In addition to the above types, Texas also has some 10 students' cooperatives, the greatest development of which is at Texas A & M College where one association operates 25 rooming and boarding houses for students. Another students' association operates a flying (aviation) service. In the State there are also perhaps a score of cold-storage associations, in addition to a number of locker plants operated by associations whose main line of activity is marketing or purchasing. Texas also has a unique recreation cooperative—an association which purchased land and built an arena where the members practice the roping of steers.

Virginia has 86 credit unions and 15 REA cooperatives, some half dozen urban stores or buying clubs, and a number of farmers' cooperatives handling petroleum products and farm and home supplies. These include several Negro store cooperatives, one of which has been operating since 1937 and has three branch stores. The most active recent development has been the erection of cold-storage locker plants—a development which has been fostered by the Southern States Cooperative, at Richmond. Until the war put a stop to civilian flying, the State also had 5 flying clubs which owned one or more airplanes which the members flew for pleasure.

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., May 20, 1947.

The Secretary of Labor:

I have the honor to transmit herewith the third issue of the bulletin on retail prices and indexes of retail prices of foods. This report covers the years 1944 and 1945.

A mimeographed report on retail prices of food, giving index numbers by groups and subgroups of commodities and average prices for individual commodities in each of 56 cities will continue to be issued monthly and will be available on request as heretofore.

This report was prepared by the Food Section, Division of Consumers Prices, Prices and Cost of Living Branch.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Retail Prices of Food 1944 and 1945

Summary of Trends in Food Prices During World War II

During the 6 years of World War II (September 1939–August 945), average retail prices of all foods advanced more than 50 per- ent. At the end of 1945 the Bureau of Labor Statistics all-foods rice index was more than 41 percent above the 1935–39 average and 4 percent below the 1920 peak. Retail food prices in 1944 were elatively stable, averaging 1.4 percent below the average for the ear 1943 and 4.8 percent below the high for World War II established May 1943, the peak of the rise that led to the President's hold-the- ne order, issued in April 1943. This stability was largely accom- lished through subsidies and OPA regulations, including commodity ollars-and-cents ceilings and the establishment of ceilings for a umber of items not previously controlled. As an integral part of e price stabilization program, subsidies were paid producers and ocessors of many foods including meats, dairy products, flour, and gar. The subsidies, which served to hold or reduce retailers' costs, abled retailers to sell at prices within the established OPA ceilings. the end of 1943, price controls were in effect for all foods priced the Bureau. With few exceptions, these controls continued in eration during 1944 and 1945. Prices for 1945, on the average, re higher than in 1943 or 1944, although the May 1943 peak was ver equaled in any month in the two following years.

Production of foods in 1945 remained at high levels but fell far rt of demand as Government purchases for military and lend-lease ount took a considerable part of the available supplies. Many ds continued to be rationed during 1944 and most of 1945. Short- s of certain foods were intensified in 1944, and some foods became remely scarce in 1945. Despite the reduction of rations, supplies, many instances, were inadequate to fulfill the ration allowances. -day brought no immediate relief from the acute shortages of meats, and oils, sugar, cheese, condensed and evaporated milk, eggs, ltry, processed fruits and vegetables, and canned fish.

ood supplies, except for sugar, and fats and oils, improved consid- ly after VJ-day as a result of the curtailment of military require- ts and the cancellation of most contracts for lend-lease purchases. ioning of canned fruits and vegetables was removed on VJ-day and rationing of meats, canned fish, butter, and fats and oils was eliminated in November 1945. Sugar was the only food still being rationed at the end of 1945. OPA price controls continued in effect and the elimination of rationing had no specific reaction on prices.

Table 1 presents indexes of retail prices of all foods from 1913 through 1945. During World War I (1914–18) annual average food costs rose about 64 percent. During World War II (1939–45) annual average food costs advanced less than 47 percent. However, the average of 139.1 percent of the 1935–39 base, reached by the index in 1945, was 3.5 percent higher than that for 1918, the final year of World War I. Retail food prices mounted rapidly and unceasingly during most of World War I. By contrast, in 1944, food prices averaged 1 percent lower than in 1943, and in 1945, the final year of World War II, food prices were maintained at levels only slightly higher than the average for 1943.

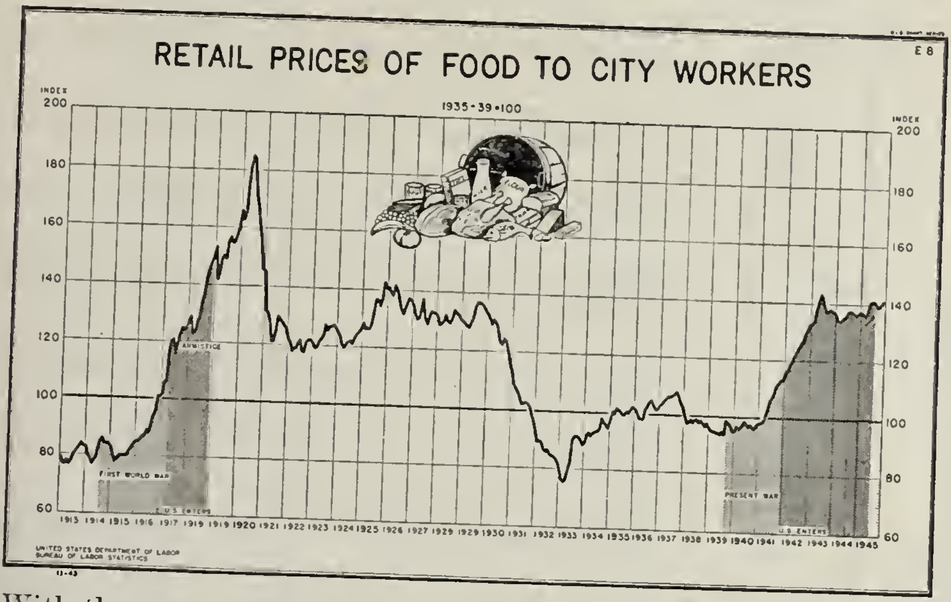
Food Prices During the Years 1944 and 1945

Fluctuations in the all-foods index during 1944 and 1945 were caused partly by the regular seasonal variations in prices of certai foods such as eggs and fresh fruits and vegetables and partly by othe factors such as adjustments in price controls and subsidies. In Apri 1944, the OPA instituted a system of seasonal pricing for fresh fruit and vegetables whereby ceiling prices could be revised each week an adjusted to restore the usual seasonal price patterns. Seasonal pricing of eggs had been in effect since March 1943.



With the exception of only 2 months, food prices declined steadily for the first 10 months after May 1943, and by March 1944 were 6 percent below the World War II peak. The decline during the first quarter of 1944 was chiefly the result of lower prices for eggs, of which there was an abundant supply, and fresh fruits and vegetables, for which OPA, in January 1944, issued new maximum prices at wholesale levels. Prices of cereals and bakery products declined slightly during this period after a 3-year uninterrupted advance. A subsidy granted to millers of wheat flour in December 1943 stopped the steady climb of prices in this group and permitted processors to pay farmers more for their grains.

After March 1944, prices rose steadily until in August they were 2.7 percent higher than the low in March, a result of seasonal increases n egg prices and higher prices for fresh fruits and vegetables, particuarly oranges, potatoes, and spinach. Prices of foods then receded—xcept in November and December—until March of 1945, when they vere about 5 percent below May 1943. During the next 4 months, hey again advanced sharply, this time to within 1 percent of the ay 1943 peak. These advances, through July 1945, were due chiefly o rapidly rising prices of fresh fruits and vegetables such as apples, ranges, potatoes, and green beans.

Table 2 shows the indexes of retail prices of foods by commodity roups for the years 1923 through 1945 and for each month in 1944 nd 1945. In 1945, the average cost of all foods combined was higher an at any time in the preceding 21 years (1923–44). The high averge cost of all foods in 1945 resulted largely from the high levels ached by prices of meats, dairy products, and eggs.

---

[1] Aggregate costs in each city, weighted to represent total purchases of families of wage earners and lower-salaried workers, have been combined with the use of population weights.

[2] Comparable indexes for the years 1923–34 have been computed by converting indexes from the 1923–25 base to the 1935–39 base.

Changes in Food Prices by Cities

Retail food prices on the average for large cities in the United States advanced a moderate 3.1 percent between December 1943 and December 1945, but price increases among cities varied considerably. During this 2-year period, the greatest rise in food prices occurred on the Pacific Coast—7.2 percent in San Francisco, 6.2 percent in Portland (Oreg.), and 5.3 percent in Seattle. There were marked increases in 1944 and 1945 in Memphis, Jacksonville, Washington, Baltimore, Milwaukee, and Providence. The smallest changes in food prices were in New England. In Bridgeport and Portland (Maine) prices increased less than 1 percent, and in New Haven prices declined nearly 1 percent. Buffalo food prices were no higher in December 1945 than in December 1943 and prices in St. Paul, Norfolk, and Louisville advanced negligibly.

Among the 51 cities for which food-price indexes are based on the period 1935–39, prices in December 1945 ranged from 34 percent to more than 54 percent above the levels prevailing in the base period, with an average increase of 41.4 percent over the base period. Greatest increases over this longer period prevailed in Pacific Coast, East South Central, and South Atlantic cities and the smallest increases were in New England and certain scattered cities such as Columbus (Ohio), Omaha, and St. Paul.

The indexes of average retail prices of foods, by cities and by months for 1944 and 1945 are presented in table 3.

---

[1] Aggregate costs of 61 foods in each city, weighted to represent total purchases of families of wage earners nd lower-salaried workers, have been combined for the United States with the use of population weights.

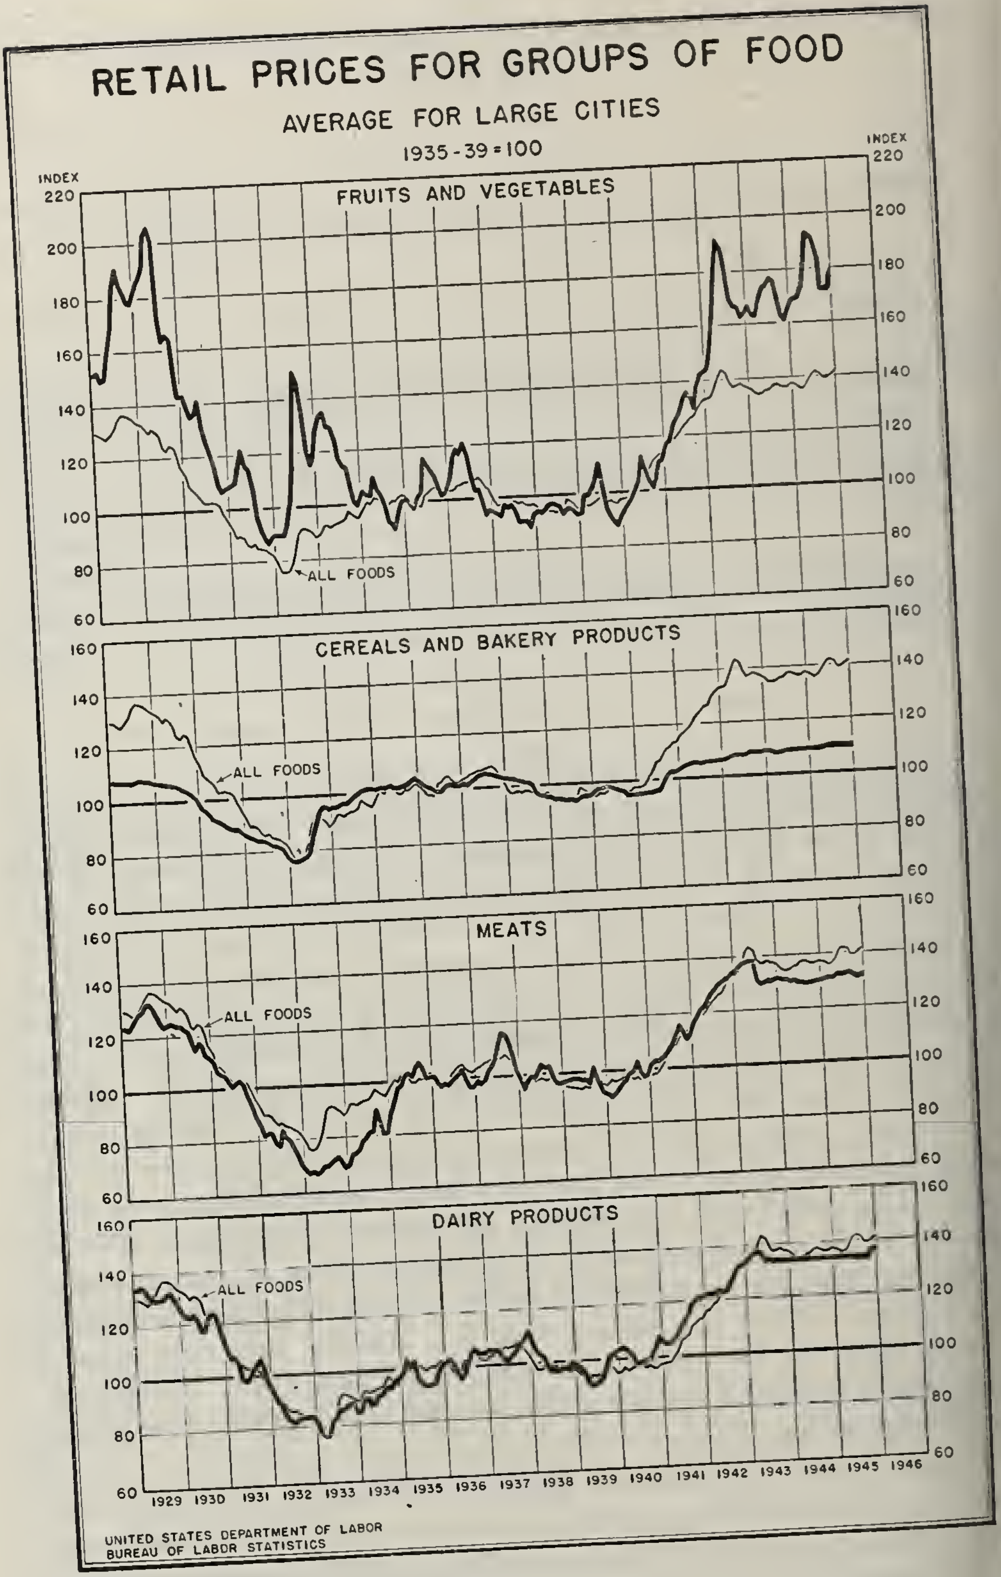
[2] June 1940=100.

[3] Includes Portsmouth and Newport News, January to August 1945 inclusive.

Trend of Prices for Major Food Groups

Cereals and bakery products.—The retail prices of cereals and bakery roducts, which had been rising steadily from 1939 through 1943, eveled off in 1944 and rose less than 1 percent in 1945 to a level 7 percent above that of August 1939. Flour prices, which were abilized in February 1944 by a subsidy payment to millers uthorized in November 1943), remained unchanged until June, hen prices declined following further ceiling reductions made after lowing additional subsidies to millers in the Eastern and Central ates. Flour prices in 1945 remained practically unchanged. Maca- ni prices were relatively stable during the period, fluctuating within 2-percent range during 1944 and even less in 1945. In the cereals oup, prices of wheat cereal and corn flakes remained relatively con- ant while rolled oats rose sharply (17 percent) from April 1944 to e end of the year, but leveled off in 1945 at about 2 percent above ecember 1944. Rice fluctuated within a range of 2.4 percent during 2 years. Prices of pancake flour rose slightly, and were some 5 rcent higher in December 1945 than in January 1944. Corn-meal ces rose 8 percent from March to October 1944 but were practically changed during 1945.

Prices of bakery products in general and bread in particular were d strictly in line during 1944 and 1945 as a result of the subsidies on ir, reflecting the Administration's effort to keep prices of basic foods low levels.



RETAIL PRICES FOR GROUPS OF FOOD

1935-39=100

FRUITS AND VEGETABLES

CEREALS AND BAKERY PRODUCTS

MEATS

DAIRY PRODUCTS

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Meats.—As a group, meat prices during 1944 and 1945 failed to equal the World War II high of mid-1943. By the end of World War II, however, the average price of meats was some 37 percent higher than in August 1939, the month preceding the war's start.

Meat packers continued to receive subsidy payments during 1944 and 1945. With heavy meat production late in 1943 and in the spring of 1944 and with crowded storage facilities, ration points were removed from all meats except beef roasts and steaks during May and June 1944. However, on July 30, 1944, beef set-asides for military and lend-lease were increased to 45 percent of production and again increased in August to about 50 percent of production. By the end of 1944, rationing had been restored for approximately 85 percent of all meats sold at retail. Supplies for civilian consumption were not adequate to meet the record demand and meat shortages of several months duration developed in retail stores at various times during 1944 and 1945. Partial relief from the meat scarcity occurred after VJ-day for a short period.

Beef, veal, and pork prices declined generally during 1944. Beef and veal were lower from January to October as prices for practically all cuts declined or remained unchanged. In the last quarter of 1944 record supplies of beef failed to meet demand and prices advanced moderately until April 1945. With the end of the war in the Pacific, supplies for civilians increased materially as military and lend-lease set-asides were decreased and prices of beef and veal declined slightly from May 1945 through the end of the year. Pork prices were stable throughout the year 1945 at about the same level as 1944 but 6 percent below that of 1943.

Lamb prices rose steadily during the first 7 months of 1944 and leveled off until December. Between December 1944 and August 1945, lamb prices advanced somewhat and remained at the August level (which was 4 percent below May 1943) through December. Sheep and lamb slaughter set a record in the first 4 months of 1945, but the supply was not great enough to offset the heavy civilian demand: In August 1945, direct subsidy payments to producers replaced payments to slaughterers, in order to meet increases in costs of production without reflecting higher prices to consumers.

Chicken prices followed their regular seasonal pattern for the first 9 months of 1944 but failed to decline seasonally in the final months of the year when there was heavy demand for poultry as a substitute or scarce meats. Moreover, production in 1944 was 20 percent below he record year 1943. The seasonal price pattern was at a higher evel in 1944, however, as average prices for 1944 were 3.3 percent bove those of 1943. Prices in 1945 followed about the same pattern s 1944 prices but again at a higher level (about 2 percent). Retail prices of roasting chickens in August 1945 averaged 47.6 cents a pound, the highest price recorded by the Bureau since April 1920.

Dairy products.—Dairy product prices remained stable during 1944 and 1945 except for the last 2 months of 1945 when the butter subsidy was removed, raising the average price to consumers from 50.0 to 54.7 cents a pound, a 9-percent increase. In December 1945, prices of dairy products were 46 percent higher than during August 1939. During the latter part of 1945, butter production dropped as producers diverted butterfat into other lines such as cream and ice cream. Dairy products as a whole for civilian consumption were in short supply during most of the 2-year period. High ration points were necessary to distribute available butter and cheese supplies among civilians as various war requirements took a large part of total production. After VJ-day, cheese and evaporated milk were removed from rationing and the point value of butter was reduced.

Eggs.—A fairly large supply of eggs in the spring and early summer of 1944 postponed the usual seasonal price increases until July. The seasonal peak of prices in December 1944, fell a little short of the high established in November 1943. Prices then declined until April 1945, but maintained a level some 10 percent higher than the low of May 1944. Average prices of eggs more than doubled during World War II and by December 1945 consumers paid 113 percent more for eggs than in August 1939. At the close of the year 1945, average prices of eggs were 68.2 cents a dozen, higher than at any time during World War II. Supplies of better grade eggs were not adequate but the lower grades became more plentiful when the army canceled its dried egg program shortly after VJ-day.

Fruits and vegetables.—By January 1, 1944, all fruits and vegetables commonly purchased by consumers had been brought under price control. Controls, coupled with larger supplies during 1944, held prices for the group at approximately the same average as in 1943. By the end of 1945, however, fruit and vegetable prices had increased to a level nearly double that preceding the war in August 1939.

Apple prices, which held fairly close to the usual seasonal trend during 1944 as the result of a good crop, began to show substantial increases after March 1945, when it became apparent that a warm March followed by frost in April and early May in the apple-producing States of the East and Middle West would cut the crop considerably. This short crop was half as large as the 1944 crop, with the result that the average price of apples rose to 14.3 cents a pound in December 1945, or about 28 percent over the 1944 level. Orange prices were increased during the winter months under a “disaster’ adjustment, in effect from November 6, 1944, to March 1, 1945 which was instituted because of the extensive crop damage resulting from the Florida hurricane in September of 1944. With the indication of bumper crops in the fall and declining prices, ceilings were finally suspended for a 2-month period beginning in mid-November.

Average prices of fresh green beans and carrots in 1944 were unchanged from 1943, while cabbage prices averaged 25 percent lower, lettuce 18 percent, spinach and onions 8 percent. Production of most vegetable crops was not quite as high in 1945 as in 1944, resulting in higher prices during the first half of the year. Ceilings on cabbage and green bean prices were removed on June 6 and July 1, 1945, respectively. There was an immediate increase of 55 percent in cabbage prices and 37 percent in green bean prices. By October 1945, prices for both of these vegetables had fallen below those in effect immediately before the removal of ceilings. Prices of white potatoes were high during 1944, as a result of increased ceilings permitted on early potatoes to encourage production, and upward adjustments in ceilings for potatoes from Eastern and Midwestern States because of the drought. Throughout the first 7 months of 1945, potato prices held at levels higher than those of 1944, but declined sharply in August and September as larger supplies became available with the curtailment of Government purchases. "Disaster" ceilings were eliminated in early August, and remaining ceilings suspended September 14.

Prices for canned fruits and vegetables were relatively stable in 1944 and in 1945 were at approximately the 1943 level. Prices declined slightly from January to July 1944, and then rose slowly to November 1945, to a level about 1 percent higher than in July 1944. Production of canned fruits never equaled demand, but supplies of most canned vegetables were available during the 2-year period.

Beverages.—Coffee prices were stable during 1944 and 1945, with average prices in December 1945 less than a cent higher per pound than in January 1944. Brazil continued to export coffee when shipping facilities were available, paying a subsidy to producers to make up for increased costs which would have prohibited profitable sale to the United States at our rigid ceiling prices. Trading with Colombia continued slow and in the summer of 1945, Great Britain and other European countries bid prices upward by 1¼ cents per pound, thus reducing offerings to the United States. After VJ-day, offerings were practically nonexistent as the South American countries awaited developments on ceiling prices in the United States. Tea prices remained stable at ceilings and although tea continued to be allocated under international agreement, the supply situation had improved sufficiently by January 1945 to allow suspension of the order restricting packaging and distribution. Supplies of cocoa continued to be limited, and average prices remained stable.

Fats and oils.—Declines in the price of peanut butter from January to August 1944 were responsible for slight price decreases of fats and oils as a group. Between August 1944 and December 1945, the group index increased less than 2 percent. Again peanut butter prices were primarily responsible, as prices for this commodity rose sharply at the end of 1945 when the subsidy was removed and OPA permitted price increases. Prices of lard, shortening, oleomargarine, salad dressing, and cooking and salad oils were lower by the end of the year 1945 and were removed from rationing in November 1945.

Sugar and sweets.—Prices for sugar, corn sirup, and molasses remained stable throughout the 2-year period 1944 and 1945. Sugar remained extremely scarce during most of the period and was the one food rationed throughout 1944 and 1945. The United States mainland and Cuba produced the bulk of the supplies available to the world as the Philippines and Pacific sources were virtually cut off. Cuban production was off sharply with no 2-year cane available for grinding. By the summer of 1945, the best producing areas of Europe had been ruined by war, and part of the already tight supplies were shipped to European countries. For the 1944–45 sugar crop, the United States paid a subsidy of $9 a ton for Cuban sugar, a subsidy of $3 a ton to processors of raw beets, and 85 cents a ton to processors of cane sugar in Louisiana.

Monthly average retail prices of individual foods for large cities combined are presented in table 4 for 1944 and 1945. Annual average retail prices of individual foods in each of 56 cities, for 1944 and 1945, are shown in table 5.

TABLE 4.—*Average retail prices of principal foods in large cities combined, by months, 1944 and 1945*

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., March 5, 1947,

The Secretary of Labor:

I have the honor to transmit herewith a report on union health and welfare plans, which consists of two articles.

The first article brings up to date collective-bargaining developments in the field. It also notes several of the medical service plans entailing a health center and the recently established United Mine Workers' program. This article was prepared in the Bureau's Industrial Relations Branch, Boris Stern, Chief.

The second article was written by Nathaniel M. Minkoff, secretary-treasurer of the New York Dressmakers' Joint Board, International Ladies' Garment Workers' Union (AFL). It treats principally of the experience of that organization with its own program and emphasizes some of the administrative problems which that union, and all unions, must encounter and solve.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 900 of the
United States Bureau of Labor Statistics

[Reprinted from the MONTHLY LABOR REVIEW, February 1947]

Union Health and Welfare Plans

COLLECTIVE-BARGAINING DEVELOPMENTS IN HEALTH AND WELFARE PLANS[1]

WORKERS covered by some type of health-benefit [2] plans negotiated
by employer and union more than doubled in number since 1945, as
evealed by recent estimates made by the Bureau of Labor Statistics.
n 1945, some 600,000 workers were so included; at present (early 1947)
pproximately 1,250,000 are covered. Except for a few outstanding
nstances, including coal mining, the plans were negotiated by the
ame unions studied in the 1945 report, and are merely extensions of
heir programs.[3]

The principal industries in which a large proportion of workers
otaling approximately 1,100,000) are covered by some type of
ealth benefit plan are clothing (men's and women's), textiles, and
al mining. Other industries in which a part of the workers are
vered (totaling over 100,000) are building trades; fur and leather;
rniture; hotel; laundry, cleaning, and dyeing; machinery (particu-

Prepared in the Bureau's Industrial Relations Branch by Lucy M. Kramer, with the assistance of Rose
eodore, under the direction of Harold S. Roberts.

See Health-Benefit Programs Established Through Collective Bargaining, Bureau of Labor Statistics
lletin No. 841 (reprinted from Monthly Labor Review, August 1945).

Most of the plans described in the 1945 Bureau of Labor Statistics report have been negotiated by the
wing unions: International Ladies' Garment Workers' Union (AFL); Amalgamated Clothing Workers
merica (CIO); United Hatters, Cap, and Millinery Workers' International Union (AFL); Textile
rkers' Union of America (CIO); United Textile Workers of America (AFL); International Fur and
ther Workers' Union of America (CIO); United Electrical, Radio, and Machine Workers of America
O); Upholsterers' International Union of North America (AFL); United Furniture Workers of America
O); Industrial Union of Marine and Shipbuilding Workers of America (CIO); Hotel and Restaurant
ployees' International Alliance and Bartenders' International League of America (AFL); United
erworkers (CIO); United Retail, Wholesale, and Department Store Employees of America (CIO);
lgamated Association of Street, Electric Railway, and Motor Coach Employees of America (AFL).
itional unions which have recently included health-benefit plans in their collective bargaining agree-
ts are: Building Service Employees' International Union (AFL); Progressive Mine Workers (Inde-
ent); United Mine Workers (AFL); United Office and Professional Workers (CIO); Brotherhood of
ters, Decorators, and Paperhangers (AFL); and United Association of Plumbers and Steamfitters
L).

larly electrical); office; paper; retail and wholesale trade; shipbuilding; and street and electric railway.

Although extensive employee coverage is found at the present time in only three industries, there are an increasing number and variety of industries in which some proportion of the workers are covered.

Types of Health-Benefit Plans

ADMINISTRATIVE CONTROL

In the Bureau's 1945 study of health-benefit plans established through collective bargaining agreements, it was found that there were three types of benefit plans—(1) those administered by the union solely, (2) plans administered jointly, and (3) programs administered by a private insurance company wherein the employer pays the premium directly or into a special premium fund. Most of the plans studied were financed entirely by the employer. This was true of all union-administered plans, of almost all jointly administered programs, and of more than half the plans administered by insurance companies.

Most of the agreements stipulate a specific percentage of the employer's pay roll (usually 2 or 3 percent) to be paid into the fund. If the contribution is not specified, the employer either defrays all expenses or supplements employee contributions as required. The health-benefit plans included weekly cash benefits during illness and disability caused by nonoccupational accidents, hospital and surgical expenses, and sometimes payment of doctor bills. In most cases dental care and preventive medicine were not usually included.

UNION HEALTH CENTERS

The first Union Health Center of the International Ladies' Garment Workers' Union (AFL) was established in 1912 in New York City, and still functions. In addition to furnishing medical care to garment workers at the Center, it inspects sick-benefit plans and serves as a health education center. It is concerned primarily with ambulatory cases—in the nature of a clinic. It does not offer service to the families, nor complete medical service to the members, and its financing varies with the craft.[4] In addition to cash benefit payments, and clinical medical services, the program provides some preventive medical care. The eye conservation plan, which provides that every shop is to be visited and each worker examined, is unique.[5] For 1 years the Center also provided dental care, but discontinued this service for organizational reasons.

[4] Health Program of International Ladies' Garment Workers' Union, by L. Price, in Monthly Lab Review, October 1939; The Employee's Viewpoint on Group Hospitalization and Medical Care, by Held, American Management Association (New York, 1946, Insurance Pamphlet No. 65).

[5] Social Welfare Through Collective Bargaining, by Julius Hochman (1945), *in* Collective Bargain Negotiations and Contracts (p. 13:101), Bureau of National Affairs, Washington.

The New York Union Health Center, administered and financed to some extent jointly by labor and management, was not the result of collective bargaining originally. Similar health centers, however, have been established recently, through such negotiations, in Philadelphia, Fall River, Boston, and other smaller communities throughout the country.[6] Furthermore, when the joint labor-management health programs were incorporated into collective agreements in the needle trades in recent years, the health center became the central agency for the administration of the health-benefit program. Until 1943 the New York Center was financed by local union contributions. Since the incorporation of health-benefit funds (financed by employer contribution) into the agreements, however, a large part of the Center's financial support has come from these funds.

ST. LOUIS PLAN

A recent health-benefit plan negotiated by the St. Louis Joint Council, United Retail, Wholesale, and Department Store Employees (CIO), referred to as the St. Louis Plan, is of interest in that a health nstitute was established, through employer contribution, which offers omplete medical services. Every medical bill of members and their amilies, for service in the home, hospital, or clinic, is to be met by he St. Louis Labor Health Institute. The organizational plans as utlined in 1945 would open the institute not only to union members nd their nonvoting families, but also to outsiders as nonvoting aproved participants. This may result in a union health-benefit plan hat will include many unions jointly in the St. Louis area.

COAL MINERS' WELFARE FUNDS

In coal mining, both anthracite and bituminous, the coal miners cured, as a result of negotiations in May and June 1946, provisions their current agreements whereby about 450,000 miners (375,000 tuminous, 75,000 anthracite) in 3,000 mines in 23 States are to hieve a considerable measure of security through the operation of ree welfare funds.[7]

In the soft-coal industry (Government operated), one fund, designted as a "welfare and retirement fund," is to be raised by levying ax of 5 cents on each ton of soft coal produced. It is to be admin-

or a brief discussion of the 1946 soft-coal negotiations and agreement, see The Changing Status of minous Coal Miners, by Witt Bowden, Monthly Labor Review, August 1946 (reprinted as Bulletin 882). See also New York Times, June 27, 1946. The provisions of the health and welfare program e contract are given in detail on pp. 7-9.

istered by three trustees—one appointed by the U. S. Coal Mines Administrator, one by the union, and one jointly. A second fund, designated as a "medical and hospital fund," is to be accumulated from wage deductions presently being checked off from miners' wages, or authorized in the future by the union. This fund is to be turned over to the union, and is to be administered by trustees appointed by the president of the United Mine Workers of America (AFL). The agreement calls for cooperation between the trustees of the two funds.

For the anthracite industry, a fund is to be raised similarly by a tax of 5 cents on each ton. This is a welfare and retirement fund, and is to be administered by three trustees—two to be appointed by the president of the United Mine Workers and one by the operators.

The technique of levying a tax on coal produced for the establishment and maintenance of a welfare fund is one that has been in existence in countries other than the United States for a number of years: Great Britain has had such a practice since 1920, New Zealand since 1925, the Netherlands since 1936, and British India and Spain more recently.[8]

Current Interest in Welfare Negotiations

Some voluntary prepaid medical-care plans,[9] entirely employer-sponsored or sponsored entirely by unions (as consumers), were in existence for many years prior to World War II—in at least one outstanding case such a plan was included in an agreement as a result of an arbitration award as far back as 1926.[10] It was during the recent war period, however, that the inclusion of health-benefit plans in union agreements gained headway.

Whether it was the national wage stabilization policy primarily which encouraged health and welfare benefits in lieu of wage increases during this period, or the necessity to maintain and increase wartime production by reducing the loss of man-hours caused by illness, or the heightened social awareness of the need for security for the wage earner, the fact remains that at the present time an increasing number of unions have such health and welfare clauses in their contracts, or have indicated their desire to negotiate for such provisions.

---

[8] Welfare Provisions for Miners in Six Foreign Countries, Monthly Labor Review, June 1946.

[9] Voluntary prepaid medical-care plans may be classified, according to Margaret C. Klem, Chief of the Medical Economics Section of the Social Security Administration, into six types: industrial, medical society, or consumer-sponsored plans, private group clinics, Government plans, and Farm Security Administration plans.

Industrial plans, those established in connection with industry, and consumer-sponsored plans established by labor organizations, are the two types pertinent to the current analysis.

Industrial plans include those initiated by the employer alone, as well as plans put into effect by co lective bargaining. Of the 115 industrial medical-care plans studied in 1945 by Margaret C. Klem, in the costs were borne entirely by the employer, in 49 entirely by employee pay-roll deduction, and in by the two jointly. (Prepayment Medical Care Organizations, Social Security Board, Washington, 194 Bureau Memo. No. 55, p. 4.)

[10] In 1926, the Amalgamated Association of Street and Electric Railway employees secured from th Chicago Rapid Transit Co. a clause requiring the latter to bear the entire sickness and life insurance f its employees. (Beneficial Activities of American Trade-Unions, Bureau of Labor Statistics Bullet No. 465, 1928, p. 31.)

The potential role of health and welfare plans in collective bargaining was apparent in the last convention of the American Federation of Labor, held in Chicago in October 1946, when President Green, in his keynote speech, stated:

> I say to you * * * that that objective [the creation of welfare funds] will now be the objective of organizations affiliated with the American Federation of Labor; we must establish in this Nation security in every condition of life—old age, illness, and infirmity—and in addition we must provide hospitalization and nursing facilities and medical care for every man and woman in the United States.[11]

The Congress of Industrial Organizations, at its recent convention held in Atlantic City in November 1946, adopted a broad resolution on various aspects of security through collective bargaining, which concluded:

> The CIO intends immediately to develop a broad program so that workers may be given a rounded protection in their living standards through collective argaining contracts providing for adequate pension plans, health insurance lans, group hospitalization plans, and the guaranteed minimum annual wage.[12]

Current demands for inclusion of employee welfare clauses in union greements are recognized by management. Research services used argely by employers [13] each have devoted considerable space in their urrent loose-leaf publications on labor relations to employee welfare nd health-benefit plans in collective bargaining—the techniques of argaining, the types of plans, the coverage, etc.[14]

The March 1946 conference of the American Management Associaon devoted time to trends in employee benefits, and heard a detailed port by Adolph Held, International Ladies' Garment Workers' nion official, on the Employee's Viewpoint on Group Hospitalization d Medical Care,[15] based on his experience as director of the Inter-

See services of Research Institute of America (New York); Bureau of National Affairs (Washington); ntice-Hall (New York).

The RIA Labor Coordinator (Vol. 2, p. 38,005) in its Employee Welfare section, reminds management "employee welfare plans are no longer fringe issues. You must be prepared when union demands nade. What factors do you have to consider in evaluating a plan? Do you know the union arguments vor of these plans, and, what's more, do you know the answers? Can you include your nonunion loyees in a plan the union wants, and how is this done?" e also footnote 5.

Trends in Workmen's Compensation and Employee Benefits, American Management Association, York, 1946 (Insurance Series No. 65).

national Ladies' Garment Workers' Union Welfare and Health Benefits Department.

At the recent meeting of the American Medical Association on industrial health, held in Boston, a panel discussion was devoted to New Horizons in Industrial Health and Welfare, in which health-benefit plans played a large part, particularly those achieved through collective bargaining.[16] The American Medical Association, in its November 30, 1946, issue of the Journal, devoted to industrial health, editorializes as follows:

> In spite of impending legislation, health and welfare are likely to be important factors in future collective bargaining. Labor may ask for greater direct participation not only in industrial medical service but in plans for general medical care. Both the Council on Industrial Health and the Council on Medical Service [of the Association] have been actively concerned with the medical implications in the coal-mine wage agreement and the probable extension of similar contracts to other occupational groups. Herein lie many opportunities for constructive medical leadership.[17]

Outlook for Health-Benefit Plans

There is no doubt, from past practice and current statements of unions, from recent management concern with welfare funds and their bargaining importance, from recent interest of the medical profession in the role of labor and management in industrial health, from the general interest of a considerable portion of the public in the Nation's health,[18] that welfare funds and health benefits will play an increasingly important role in future contract negotiations.

The increasing importance of welfare funds is generally accepted. However, the trend in financing such funds is not so clearly defined as to the relation of the employer-to-employee contribution. The establishment and extension of welfare funds through employer contributions were given impetus during the war years. In many instances, these payments were made in lieu of wage increases,[19] and employers generally assumed full financial responsibility.

Postwar conditions may put a new emphasis, not so much on welfare funds, but on their financing. With the elimination of the wage stabilization policy, with an increased labor force, and with the modification in tax exemption, the question which may receive greate attention in future negotiations may be the relative proportions in employer-employee contributions to welfare funds.

Sample Welfare Clauses in Specific Agreements

PHILADELPHIA BEDDING MANUFACTURERS' ASSOCIATION AND UPHOLSTERERS' INTERNATIONAL UNION OF NORTH AMERICA (AFL)

The employer hereby agrees to pay to the Upholsters' International Union Social Security Department, each and every month, in advance, between the first and fifth day of every month, beginning with ---------- 19--; a sum equaling 3 percent of the gross wages earned by his employee-members of this union. The said sum of 3 percent shall be calculated on the basis of the total aggregate wages earned by said employee-members during the pay periods of 4 or 5 weeks, terminating during the preceding calendar month.

The above described sum of 3 percent shall be paid by the employer as a contribution to the Social Security Fund of the Upholsterers' International Union of North America above described. In consideration for the payment of said contribution, the union agrees to extend, beginning the same date the employer's first contribution is due as set forth in the preceding paragraph, the benefits of said fund to said employee-members, in accordance with the rules and bylaws under which said fund is administered, and in accordance with the general laws of the International.

The union has contracted or will contract for the issuance of a blanket-coverage insurance policy or policies to provide for the payment of the various benefits as therein provided; a policy now being in force with the ------------- Co. It is agreed that the premiums for the maintenance of a group policy or policies on behalf of the employee-members shall be paid out of the periodic contributions paid by the employer as above described. The rights and duties of all parties, including the union, the employer, and the employee-members, shall be governed by the provisions of said blanket coverage policy.

The union agrees that the program of social security benefits hereinabove described shall be maintained in full force and effect for the entire period of time during which this supplemental agreement is in effect and the terms hereof fully complied with in all respects by the employer.

The 3 percent contribution of the employer to the social security plan is not o be increased during the life of this agreement; if the cost to the union is decreased, then the contribution by the employer is to be reduced by an equivalent mount. Two-thirds of the entire contribution is to go toward the payment of ccident and health insurance covered by the provisions of said policy, and the emaining one-third of the entire contribution goes toward the payment of death enefits as provided by the Social Security Department of the union and for the dministrative expenses of said department.

. S. COAL MINES ADMINISTRATOR AND UNITED MINE WORKERS OF AMERICA (AFL)

[Bituminous-coal mines]

ealth and welfare program

There is hereby provided a health and welfare program in broad outline—and is recognized that many important details remain to be filled in—such program consist of three parts, as follows:

(a) *A welfare and retirement fund.*—A welfare and retirement fund is hereby eated, and there shall be paid into said fund by the operating managers 5 cents r ton on each ton of coal produced for use or for sale. This fund shall be managed by three trustees, one appointed by the Coal Mines Administrator, one appointed by the president of the United Mine Workers, and the third chosen by the other two. The fund shall be used for making payments to miners, and their dependents and survivors, with respect to (1) wage loss not otherwise compensated at all or adequately under the provisions of Federal or State law and resulting from sickness (temporary disability), permanent disability, death, or retirement, and (2) other related welfare purposes, as determined by the trustees. Subject to the stated purposes of the fund, the trustees shall have full authority with respect to questions of coverage and eligibility, priorities among classes of benefits, amounts of benefits, methods of providing or arranging for provision of benefits, and all related matters.

The Coal Mines Administrator will instruct the operating managers that the obligation to make payments to the welfare and retirement fund becomes effective with reference to coal produced on and after June 1, 1946; the first actual payment is to be made on August 15, 1946, covering the period from June 1 to July 15; the second payment to be made on September 15, covering the period from July 15 to August 31; and thereafter payments are to be made on the 15th day of each month covering the preceding month.

(b) *A medical and hospital fund.*—There shall be created a medical and hospital fund, to be administered by trustees appointed by the president of the United Mine Workers. This fund shall be accumulated from the wage deductions presently being made and such as may hereafter be authorized by the union and its members for medical, hospital, and related purposes. The trustees shall administer this fund to provide, or to arrange, for the availability of medical, hospital, and related services for the miners and their dependents. The money in this fund shall be used for the indicated purposes at the discretion of the trustees of the fund; and the trustees shall provide for such regional or local variations and adjustments in wage deductions, benefits and other practices, and transfers of funds to local unions, as may be necessary and as are in accordance with agreements made within the framework of the union's organization.

The Coal Mines Administrator agrees (after the trustees make arrangements satisfactory to the Coal Mines Administrator) to direct each operating manager to turn over to this fund, or to such local unions as the trustees of the fund may direct, all such wage deductions, beginning with a stated date to be agreed upon by the Administrator and the president of the United Mine Workers: *Provided*, however, that the United Mine Workers shall first obtain the consent of the affected employees to such turn-over. The Coal Mines Administrator will cooperate fully with the United Mine Workers to the end that there may be terminated as rapidly as may be practicable any existing agreements that earmark the expenditure of such wage deductions, except as the continuation of such agreements may be approved by the trustees of the fund.

Present practices with respect to wage deductions and their use for provision of medical, hospital, and related services shall continue until such date or dates as may be agreed upon by the Coal Mines Administrator and the president of the United Mine Workers.

(c) *Coordination of the welfare and retirement fund and the medical and hospital fund.*—The Coal Mines Administrator and the United Mine Workers agree to use their good offices to assure that trustees of the two funds described above will cooperate in and coordinate the development of policies and working agreements necessary for the effective operation of each fund toward achieving the result that each fund will, to the maximum degree practicable, operate to complement the other.

Survey of medical and sanitary facilities

The Coal Mines Administrator undertakes to have made a comprehensive survey and study of the hospital and medical facilities, medical treatment, sanitary, and housing conditions in the coal-mining areas. The purpose of this survey will be to determine the character and scope of improvements which should be made to provide the mine workers of the Nation with medical, housing, and sanitary facilities conforming to recognized American standards.

STANDARD CONTRACT: MEN'S AND BOYS' CLOTHING MANUFACTURERS AND AMALGAMATED CLOTHING WORKERS OF AMERICA (CIO)

Commencing on the pay day for the week of December 10, 1945, and weekly thereafter, the employer shall pay to the trustees (hereinafter called the trustees) designated under a new agreement and declaration of trust dated as of December 10, 1945 (a copy of which said new agreement and declaration of trust dated as of December 10, 1945, has been exhibited to the employer and approved by the employer) the terms and provisions of which new agreement and declaration of trust are herein specifically incorporated by reference, sums of money determined as follows:

(a) Two percent of the wages payable for the preceding pay period to all the employees of the employer, plus

(b) Three percent of the wages payable for the preceding pay period to those employees of the employer who are members of the union.

All of the foregoing sums shall be administered and expended by the trustees pursuant to the provisions of the said new agreement and declaration of trust (dated as of December 10, 1945) for the purpose of providing benefits upon their retirement because of old-age, and life, accident and health insurance, and such other forms of group insurance for medical care and hospitalization as the trustees may reasonably determine, to members of the union employed by the employer, and members of the union employed by other employers who are members of the group embraced within the general plan in the men's and boys' clothing industry.

The employer shall furnish to the trustees, upon request, such information and reports as they may require in the performance of their duties under any of the agreements and declarations of trust. The trustees, or any authorized agent or representative of the trustees, shall have the right at all reasonable times during business hours to enter upon the premises of the employer and to examine and copy such of the books, records, papers, and reports of the employer as may be necessary to permit the trustees to determine whether the employer is fully complying with the provisions of paragraph 3 [above].

No employee shall have the option to receive instead of the benefits provided for by any of the agreements and declarations of trust any part of the contribution of the employer. No employee shall have the right to assign any benefits to which he may be or become entitled under any of the agreements and declarations of rust or to receive a cash consideration in lieu of such benefits either upon termination of the trust therein created, or through severance of employment or otherwise.

* * * * * * *

In the event that the union receives written notice from one or more of the rustees, designated by the trustees for that purpose, that the employer has ailed to pay in full any sum due the trustees under paragraph 3 and that such ailure has continued for 5 days, the union may direct its members to discontinue ork in the plant of the employer and to discontinue work upon clothing being anufactured for the employer by contractors until all sums due from the employer under paragraph 3 above have been paid in full. The remedy provided for in this subparagraph shall be in addition to all other remedies available to the union and the trustees and may be exercised by the union, anything in the collective bargaining agreement to the contrary notwithstanding.

The trustees, in their own names as trustees, may institute or intervene in any proceeding at law, in equity, or in bankruptcy for the purpose of effectuating the collection of any sums due to them from the employer under the provisions of paragraph 3.

In the event that legislation is enacted by the Federal Government levying a tax or other exaction upon the employer for the purpose of establishing a federally administered system of life, health, accident, medical care, or hospitalization insurance under which the employees of the employer are insured, the employer shall be credited against the sums payable under paragraph 3 for each pay period, with the amount of such tax or exaction, payable by him for such pay period, provided that the amount of such credit shall in no event exceed 2 percent of the wages payable to the employees of the employer for such pay period.

ATLANTIC COTTON FELT CO., NEWARK, N. J., AND UNITED FURNITURE WORKERS OF AMERICA (CIO)

The employer hereby agrees, as long as this agreement remains in force, to contribute monthly on or before the ---------- day of each month, commencing with the effective date of this agreement to -------------- as trustees of United Furniture Workers Insurance Fund, a sum equal to 3 percent of the previous month's production pay roll, to be used by said trustees for the sole benefits of the employees covered by this agreement for the purchase of group life insurance, group accidental death and dismemberment insurance, group accident and health insurance, hospitalization insurance, and group surgical insurance, in accordance with the schedule of such respective forms of insurance attached hereto entitled "Schedule of Amounts of Insurance." It is further understood and agreed that these contributions to the above-mentioned trustees will be held and managed by them under the terms of a trust agreement drawn between the union and said trustees. (It is further understood and agreed that the employer shall be under no obligation to see to the application of moneys paid to the trustees pursuant to this paragraph for the purposes and uses above mentioned; but the union, nevertheless, agrees to render reports at regular intervals to the employer respecting application of the moneys received and benefits paid.)

The employer agrees to make available to the union or the trustees above-named any and all records of employees hired, classifications of employees, names, social security numbers and amount of wages paid, and social security pay roll records, that the union or the trustees may require in connection with the sound and efficient operation of the trust fund above mentioned, or that may be required by the insurance companies covering the employee.

TRADE-UNION WELFARE PROGRAMS [1]

By NATHANIEL M. MINKOFF, *Secretary-Treasurer, Joint Board Dressmakers' Union, International Ladies' Garment Workers' Union*

Development of the Movement

GROWING preoccupation of unions with health and welfare programs is not a new departure in labor policy; this preoccupation dates back to the early days of trade-unionism in this country.

The first organizations of workers in the United States, as in Great Britain, were generally mutual aid associations, such as loan, sick benefit, or burial societies. Overt organization for collective bargainng was still forbidden by law, and these mutual aid groups, almost rom the start, assumed what today would be called "industrial functions," in addition to the narrower tasks of providing the mutual aid for which they were ostensibly formed. It was these mutual aid groups which initiated the modern labor movement, and from them the trade-unions of today have derived the habit of referring fraternally to members as brothers and sisters, as well as some of the ceremonials and rituals of initiation and procedure.

---

[1] This article deals primarily with the experience of the New York Dress Joint Board of the International adies' Garment Workers' Union.

The views expressed are those of the author and are not necessarily shared by the Bureau.

With time and favoring circumstance, the essentially industrial character of these organizations became explicit. The Philadelphia Typographical Society, for instance, organized in 1802, was incorporated in 1810 as a benevolent society. In 1833 it gave way to the Philadelphia Typographical Society whose "primary and paramount intention" was "the determination and support of adequate wages for journeymen printers." The Pennsylvania Society of Journeymen Cabinetmakers of Philadelphia (1806) was likewise formed for purely benevolent purposes. In 1829, the society constitutionally established itself "as a criterion for workmen to endeavor to settle all disputes arising between them and their employers." The Brotherhood of Locomotive Firemen and Enginemen was formed as late as 1873 as a benevolent society, and it was not until 12 years later that it assumed its role as a labor union. The Iron Molders' Union, established in 1859, operated an extensive benefit system before it assumed industrial functions. Curiously enough, all benefits were suspended by this union in 1880 on the ground that such features interfered with the industrial tasks of the organization. After a decade, however, the welfare program was resumed.

Other groups, organized in later years as labor unions in the modern sense, soon expanded their activities to include welfare programs. The Barbers' Union, set up in 1887, initiated its benefit program in 1893. The Tobacco Workers, organized in 1895, established its sick benefit program in 1896. The Plumbers' Union (1889) established its benefits in 1903. In one way or another, welfare and mutual aid programs became a recognized feature of American trade-unionism and helped greatly to give it a much needed stability in its early days.

By the end of the First World War, however, trade-union welfare activities were definitely on the decline. The attitude of the topmost labor leadership was troubled and unfriendly. In 1930, Matthew Woll stated:

> Benefit systems, where they are still in operation, are a constant source o trouble. They are encountering all of the troubles that beset unscientific insti tutions. Their assessments must be raised constantly to meet rising ages, an increases of assessments are always resented. All manner of complication result. * * * Few union operations are today productive of as much wo and uncertainty as the benefit systems that remain in operation.[2]

---

[2] Why Trade-Union Group Insurance Rather Than a Benefit Plan? (*In* The American Photo-E graver, April 1930.)

Daniel J. Tobin, president of the Teamsters' Union, said very much the same thing in recent years:

> Our advice to local unions is to keep away from the sick benefit and from the unemployment benefit as much as possible. * * * Local unions should not overload themselves with liabilities during these prosperous days. Build up your treasuries. Remember there are lean years ahead of us.[3]

Welfare programs had come to be regarded as of little importance when, in the early 1930's, union leaders, in launching their campaign to organize the mass-production industries, found to their dismay that in many instances workers were reluctant to join bona fide unions because their own "company unions" were providing them with various forms of health and welfare benefits and recreational facilities which the bona fide unions could not match. Hence, those unions which succeeded in organizing mass-production industries had to promise their newly organized members, in addition to increased earnings and shorter hours, the continuation of the welfare features to which they had become accustomed. Thus, a number of labor unions unexpectedly and sometimes unwillingly undertook social welfare programs quite out of line with their general outlook.

Stimulus Under Little Steel Formula

At this point a basic change in the nature of "union welfare programs" took place. Hitherto, the term implied plans financed by the workers themselves, through regular payments or assessments; henceforth it was to mean funds and programs financed—in part at least—by the employers, in accordance with an understanding reached through collective bargaining and often embodied in the collective agreement. The limitation of wage increases during World War II under the Little Steel Formula greatly promoted this development. Beyond the 15 percent increase above January 1941 levels uthorized for direct wage increases, it was possible to obtain indirect ncreases in the form of "fringe adjustments" including employernanced health, welfare, and vacation plans. As E. E. Witte, of the National War Labor Board, explained:

> It is clear from all these cases that the Board will not normally order an employer to institute a group insurance plan or direct the liberalization of a plan in xistence. Each case, however, will be judged on its own facts, and where it is early necessary in the interests of a fair and equitable disposition of the dispute require the employer to institute or liberalize a group insurance plan, the oard will so direct.[4]

Under the pressure of the war, and in view of the high profits which dustry was earning, management was not averse to this directive.

International Teamster, April 1944.

Daily Report on Labor-Management Problems, No. 76 (Bureau of National Affairs), April 13, 1945.

As a result, union welfare programs were initiated in many segments of the trade-union movement.

Present-Day Types of Programs

The type of welfare program in operation today varies with the circumstances in the particular industry or locality in which it functions. In some instances—for example, the erstwhile Kaiser shipbuilding enterprise on the West Coast—the program is financed entirely by deductions from the workers' earnings, but is managed exclusively by the company. The Endicott Johnson Co. of Binghamton, N. Y., has a different approach: It not only assumes the entire administration of the plan, but also furnishes all the finances as well. A third type is that maintained by the Consolidated Edison Co. of New York, whereby the program is financed by contributions from both the employees and the employer, although administration is the exclusive prerogative of the company. The fourth kind—which will be discussed here in detail—is that of the International Ladies' Garment Workers' Union local unions. Here the programs are financed entirely by management, but the day-to-day administration is left to the union, subject to review of a council on which the employers are represented.

Ladies' Garment Workers' Health and Welfare Programs

History.—The International Ladies' Garment Workers' Union entered the field of welfare programs soon after the historic cloakmakers' strike of 1910. Several local unions, notably Pressers' Local 35 and Cloak Tailors' Local 9, both of New York City, established tuberculosis benefit funds, to which each member contributed a dollar a year. Workers found suffering from tuberculosis were eligible to a cash benefit of $100, or a sojourn in the country for a minimum period of 10 weeks at the full expense of the union.

Not so long ago, it will be recalled, the needle trades constituted a thoroughly sweated industry, giving rise to the term "sweatshop." Not much attention was paid to the plight of the workers except by the weak and struggling unions (which, single-handedly, were unable to do much), and by a few reformers. Most of the garment factories in New York City were located in the tenement slums of the East Side; building piled upon building without vacant space for admitting sunshine, light, or air. Sanitary facilities were lacking. The long hours of employment and low wages compelled many workers to use the factory as a lodging. Employers did not object to this arrangement, because it saved them the expense of a watchman. There were no factory laws to observe.

Under these conditions, it was inevitable that tuberculosis should become the chief occupational disease in the garment industry. Such an environment also led to one of the most disastrous industrial catastrophes known in our country, wherein 147 young women workers lost their lives in a fire which broke out in the Triangle Waist Shop in March 1911. It was definitely established, at the criminal trial which followed, that the owners had the factory doors (including those leading to the fire escapes) locked during working hours.

These startling facts came to light as a result of an industry-wide investigation conducted by the United States Public Health Service in 1912 in cooperation with the Joint Board of Sanitary Control. This unique institution came into being as a result of the signing of the "protocol of peace," which followed the prolonged and bitter general strike of the coat and suit makers of New York in 1910. Its main objectives were the elimination of dreaded sweatshop conditions and of fire hazards.

Louis D. Brandeis, Louis Marshall, and Hamilton Holt were the chief architects of this idea. The Board was originally administered by representatives of the employers, the workers, and the public, the latter consisting of Dr. William J. Schieffelin, Lillian D. Wald, and Dr. Henry Moskowitz. Its medical director, the late Dr. George M. Price, succeeded several years thereafter in interesting the parties not only in the maintenance and observance of more desirable working conditions, but also in the improvement of the health of the workers.

UNION HEALTH CENTER

Thus, from a small beginning involving only a few thousand workers, a huge institution today, known as the Union Health Center,[5] was created. It is owned and operated on a nonprofit basis by the ILGWU. Housed at present in its own modern, fireproof 27-story building, it is serving the needs of the 150,000 ILGWU members located in the New York area. In 1945, it rendered no less than 164,636 medical services to 28,056 patients. During the same year, it handled a total of 11,881 disability cases, to whom it rendered 24,652 services. The institution is at present under the directorship of Dr. Leo Price, son of the founder and first administrator of the Center. It has a medical staff of about 100, with a lay staff of over 150.

From the public health standpoint, the Union Health Center is unique. It was the first institution of its kind in the country, and its director is frequently called into consultation by government bureaus and other agencies interested in public health problems.

---

[5] See Monthly Labor Review, October 1939 (p. 811), for description of the ILGWU health program.

GROWTH OF PROGRAM

In the years that followed, local unions of the ILGWU began to inaugurate first a tuberculosis benefit fund and later a limited form of sickness insurance. Both of these benefits were financed by a 35-cent monthly stamp paid by the workers. The actual amount of benefits varied, but the high point was reached in the payment of $150 to tubercular members and a weekly sick benefit of $7 for a period of 8 to 10 weeks.

At the present time, the great majority of the ILGWU's 350,000 members, distributed in 420 separate local unions in 275 communities in 35 States and Canada, enjoy some form of health and welfare benefit.

New York Dress Joint Board

The largest single unit in this integrated union welfare program of the ILGWU is the New York Dress Joint Board, which includes three local unions (22, 60, and 89), with a membership of approximately 60,000. (Cutters Local 10, though part of the Joint Board, is for the present not participating in the program.)

When the collective agreement between the Dress Joint Board and the employers' associations in the New York dress industry was renewed on May 6, 1944, a new clause was included providing for a 3½-percent pay roll contribution by the employers to maintain a health and welfare program. The funds, according to the terms of the agreement, "shall be used exclusively for the members of the union and for the payment of the operating and administrative expenses thereof."

"The health fund," by further provision of the agreement, "shall be administered by the Joint Board, and the Joint Board shall determine what proportionate amount of the health fund shall be allocated for health benefit and what proportionate amount shall be allocated for vacation benefit. With respect to health benefits, the parties hereby create a council consisting of two representatives of the Affiliated Association, two of the National Association, and two of the Popular Association, and six representatives of the Joint Board of the Dress and Waistmakers' Union, which shall be presided over by the Impartial Chairman. The council shall have the right to determine the types and amounts of health benefits which the members of the union shall receive and which, however, shall not exceed the total amount allocated by the union for health benefit. The Joint Board shall file with the council any rules and regulations relating to health benefits which it may adopt, and amendments which it may make thereto, and shall report periodically to the council the accomplishments of the health fund with respect to health and vacation benefits. With respect to vacation benefits, the parties agree that the Joint Board shall have the right to adopt rules and regulations in connection therewith and to establish the eligibility of members of the union for benefits and the amounts of benefits to be paid them."

TYPES OF BENEFITS PAID BY THE BOARD

Benefits currently paid by the New York Dress Joint Board are as follows:

(1) *Cash benefit.*—Members who are ill and unable to work are entitled to a cash benefit of $15 a week for a period of 10 weeks each calendar year. It is paid upon certification by the medical department of the union (Union Health Center), and continues as long as the member is unable to work, up to 10 weeks.

(2) *Hospitalization.*—Members are entitled to a benefit of $5 per day for each day of hospitalization up to 60 days in any calendar year.

(3) *Surgery benefit.*—The union pays every member undergoing a surgical operation a sum varying from $10 to $50, depending upon the nature of the operation.

(4) *Medical credits.*—In addition to all the above benefits, every member of the union is entitled to $25-a-year medical service at the Union Health Center for general medical examination, special laboratory tests, or X-ray.

(5) *Maternity assistance.*—A $50 maternity benefit is paid members upon presentation of a board of health birth certificate. The plan is being enlarged to include stillbirths, etc.

(6) *Eye conservation program.*—Every member is entitled to free and unlimited eye treatment and to free eyeglasses.

(7) *Tuberculosis benefit.*—Members who are found to have tuberculosis are sent, at the expense of the fund, to any one of the many tuberculosis sanitariums with which it is affiliated, and are kept there until their health is fully restored. Those desiring to withdraw from membership and take care of their health independently of the fund's provisions are allowed a cash settlement of $250. The obvious difference in cost between an unlimited stay in a recognized health nstitution with all costs (including regular sick benefit and personal expenses) paid by the fund, and the alternative of $250 allowed a sick member who undertakes his own cure, is intended to deter members from asking for cash settlements and to encourage them to enter n institution where the chances for the arrest of the illness and its ltimate cure are so much better.

(8) *Vacation benefit.*—Every member of the union, employed or vailable for employment in the industry, is entitled to a cash vacation enefit ranging from $33 to $48, depending upon the particular craft f the worker. This sum is payable on the first of June of each year.

(9) *Death benefit.*—In addition to the $150 lump-sum death benefit paid by the home office of the ILGWU, for which the individual member pays $1 a year, most of the local unions pay an additional $150 without any contribution from the members. Death benefits, it should be noted, are not financed from the Joint Board Health Fund, but by the members' contributions supplemented by the local treasuries.

COST OF BOARD'S HEALTH AND WELFARE PROGRAM

The size and scope of the New York Dress Joint Board health and welfare system are indicated by the payment, during the first 8 months of 1946, of over $600,000 for seven kinds of health benefits (as shown by the following table) and of more than 2 million dollars in vacation benefits in 1946.

Comparative amount of health benefits paid during first 8 months of 1945 and 1946

Type of benefit	First 8 months		Increase	
	1946	1945	Amount	Percent
Total amount paid	$624, 199. 42	$393, 072. 37	$231, 127. 05	58. 8
Cash benefits	397, 042. 50	288, 224. 05	108, 818. 45	37. 8
Hospitalization benefit	82, 168. 00	40, 015. 00	42, 153. 00	105. 3
Surgery benefit	16, 980. 00		16, 980. 00	100. 0
Medical credit	83, 434. 87	37, 638. 75	45, 796. 12	121. 7
Maternity assistance	6, 725. 00		6, 725. 00	100. 0
Eye conservation program	32, 941. 95	25, 608. 57	7, 333. 38	28. 6
Tuberculosis benefit	4, 907. 10	1, 586. 00	3, 321. 10	209. 4

Per capita costs.—On the basis of the foregoing figures, it is estimated that the average cost in *health benefits* alone, excluding medical and general administration, is over $16 per member per year.

The cost is not uniform for the three local unions involved in the foregoing table Thus, Local 22, with a dues paying membership of 25,671, runs its various forms of benefits at an annual cost of $19.36. Local 89, with a membership of 30,405, averages $12.69, and Local 60, with 2,766 members, averages $19.34. The wide difference in costs between Local 89 and the other two locals is attributable largely to the fact that the former is composed of a considerably younger element; moreover, the whole benefit system is more recent in this union than in the other locals, with the result that its membership is not yet fully aware of what it has to offer, and so does not take the same advantages of the program as do the other two unions.

Actual *per capita costs* in *cash sick benefits*, including the medical fees involved in the examination of sick members, are as follows:

	1946	*1945*
Local 22	$11. 15	$8. 43
Local 60	10. 52	8. 44
Local 89	8. 45	6. 34

Cost of medical benefits (on a per capita basis) are distributed as follows:

	1946	*1945*
Local 22	$3.29	$1.64
Local 60	3.43	1.69
Local 89	.99	.32
	Claim rate per 1,000 (percent)	
Local 22	16⅔	12³⁄₁₀
Local 60	16⅓	12²⁄₁₀
Local 89	10⅘	8²⁄₁₀

General administration, including complete supervision as well as audit of employers' books, runs at the rate of 5 percent of gross collections.

A further examination of the foregoing table (p. 18) shows that as the health fund becomes better known to the members, payments increase correspondingly. This fact accounts for the 29 percent rise in the eye conservation program, wherein no change in benefit rate was made between the first and second year of operation.

Increases in the other parts of the program are due primarily to the change in schedules which went into effect on April 1, 1946, whereby the weekly rate of cash benefit was increased from $12 to $15, the hospitalization benefit from $3 to $5 per day and from 20 to 60 days per year, and medical credits from $15 to $25 per year. Two entirely new benefit forms were added—surgery benefit and maternity assistance.

There was also a substantial increase in the *vacation benefit* paid this year. From a preliminary report recently made available, it is evident that, although the total amount disbursed for vacation benefit or the full year ending May 30, 1945, amounted to $1,476,709.90, he vacation benefit paid out for the year ending May 30, 1946, mounted to at least $2,069,254.46, an increase of over 40 percent. This advance is explained in part by the fact that vacation benefits were increased by $10, and in part by the rise in the number of claimnts (51,077 to 53,503) for the benefit. The average cost of this type f benefit was about $39 per member during the 1946 period indicated.

The administrators of the health fund are not disturbed by these ncreases. The industry is still operating at a good pace and the eceipts in 1946 not only compared well with the previous year but lso showed an increase of 13.9 percent, as of August 1, 1946. As result of the added income, the health fund has been in a position to ut away a substantial reserve, from which it expects to be able to crease current benefits still further and gradually add new forms of enefits.

The types of benefits herein described are determined by the exrience which the union has gained from the operations of similar nds during the past 30 years and are also geared to the revenue derived during the past year. As already indicated, systematic upward readjustment is anticipated. Knowing the character of the industry—its sharp seasonal fluctuations and general instability—the union administration is taking a most careful attitude with respect to scales of payment since it does not want ever to be in a position which necessitates reduction in benefits.

HOW BENEFITS ARE PAID

We were faced with the problem of how to pay benefits. Instead of establishing a completely new department, with an individual record for each of the 60,000 dues-paying members, which would have required continuous posting of the members' records, we agreed to utilize the already existing sick-benefit departments of the individual locals and their records. Thus, members, who take sick, report directly to the local to which they belong. The health fund department of the locals, in accordance with uniform rules and regulations, then notifies the Union Health Center of the case. The member is examined within 3 days, and if disability is established, the first week's benefit is paid on the tenth day following the receipt of the report of illness. Thereafter, weekly checks are mailed upon the seventh day.

At the conclusion of each month, the local health fund departments submit detailed statements of disbursements to the secretary-treasurer of the Joint Board Health Fund Committee, who reimburses such amounts to the local health funds, subject to audit.

Any member who feels that he has been deprived of his rights or that he has not been paid in full for his disability, has ample opportunity to lay his grievance before his elected local officer. He can explain, in a language which both understand, his particular claim. He thus has the satisfaction of "talking it out" with the chief administrator of his local union, rather than having to be content with a mute, stereotyped form reply.

If he is still dissatisfied, he has an opportunity to appear before a committee on claims, which meets regularly in the office of the union. This committee is composed of two rank-and-file members from each of the affiliated local unions, and is presided over by the secretary-treasurer of the Joint Board. The rules and regulations of the health fund empower this committee to make whatever adjustments the facts would seem to justify.

In this fashion, we have established a machinery which allows for a centrally controlled administration and at the same time offers wide flexibility, giving the local unions a substantial degree of autonomy and the individual member a feeling that he is not hopelessly removed from the administration of his union and its funds.

Other Considerations

EMPLOYERS' COOPERATION

Obviously the comprehensive health and welfare program here outlined could not have been undertaken without the security and strong organization which the ILGWU has been able to develop in the past 30 years. When a trade-union must devote all of its energies and resources in struggling for adequate wages and decent working conditions, it has neither the time nor the means to think in terms of social welfare programs. Once it has achieved a substantial degree of unionization and control over workers in the industry, it can undertake these "extracurricular" activities, which then become a legitimate part of its industrial program.

In fairness to the employers in our industry, it should be said that they, too, are entitled to credit for the inauguration and development of our welfare program. In the course of the past 30 years of collective bargaining these employers have learned to recognize a responsibility beyond providing adequate earnings and decent working conditions to the men and women in their employ. They have become acquainted at first hand with the social and economic value of human welfare.

WIDE ACCEPTANCE OF UNION WELFARE PROVISIONS

Encouraged by the success which the ILGWU has scored in the field of social welfare, many other unions have, in recent years, succeeded in incorporating similar provisions in their collective agreements. Among them are the Amalgamated Clothing Workers of America (CIO), including its New York and Chicago divisions; Federation of Dyers, Finishers, Printers, and Bleachers of America (CIO); United Furniture Workers of America (CIO); United Hatters, Cap, and Millinery Workers' International Union (AFL); Upholsterers' International Union of North America (AFL); New York Hotel Trades Council;[6] Chain Service Restaurant Employees' Union;[6] International Jewelry Workers' Union (AFL); International Union of Mine, Mill, and Smelter Workers (CIO); and International Print-ng Pressmen's and Assistants' Union of North America (AFL). More recently this movement was spurred by the United Mine Workers of America (AFL), which in a recent agreement has provided or a minimum of social security for the hundreds of thousands of oal miners. Because of the grave industrial hazards to which miners are always exposed, this form of protection would have been esirable even before the garment workers and others began to enjoy . Henceforth welfare benefits become an important issue in employer-employee negotiations. This was made clear by President William L. Green in his report to the convention of the American Federation of Labor held in Chicago in October 1946.[7]

---

[6] Members of the Hotel and Restaurant Employees International Alliance (AFL) in Greater New York.

EFFECT OF PROGRAM ON UNION

What has been the effect of this welfare program upon the organization? Does it make for a stronger union? Definitely, yes. Among the chief factors making for the strength and effectiveness of the ILGWU have been its comprehensive benefit services, including, of course, its highly developed educational and cultural program.

In the early stages of the ILGWU, its membership was in a constant state of flux. The industry in all its branches was sharply seasonal. Shop strikes would break out on the eve of every season. The workers would obtain some wage increases here and there, only to see them disappear several weeks later. There was nothing to bind the garment worker to his union. He would join and drop out at frequent intervals. The turn-over in membership was tremendous.

With the introduction of the benefit system conditions changed radically. Today the person who joins the ILGWU has every good reason to maintain his membership even in slack periods. He no longer drops his membership at the end of the busy season as he did formerly, because today his membership is a form of security against illness, unemployment, accident, and death. This makes for stability, organizational strength, and effectiveness on the industrial field and gives the union real capacity for expansion.

New Programs Create New Problems

The administration of union health and welfare plans carries with it certain new responsibilities and creates certain new problems which are already beginning to make themselves felt.

1. I should like to stress particularly the need for actuarial experience and guidance in the operation of welfare programs. Heretofore unions have relied on whatever data they were able to obtain from governmental and private sources, together with their own meage information acquired in the course of experience. Benefit scale have been fixed simply on the basis of availability of funds. Little account has been taken of such facts as the increasing age of the membership and the consequent higher incidence of illness. Will the unions be in a financial position to pay the present benefits in th years ahead, when the needs will become greater and the means mo limited? This is but one example of the kind of questions that mu be considered. So many factors are involved that, unless the actuarial aspect is properly handled, the entire program may be jeopardize.

---

[7] See p. 5 for statement from Mr. Green's report.

2. It appears to me that the trade-unions ought to begin pooling their experience with a view to setting up definite criteria to enable welfare programs to stand the strains and stresses inevitable under our present economic set-up. It is my feeling that the more efficiently and the more scientifically our funds are administered, the more likely we are to preserve their voluntary character.

3. Another problem which has come to the fore is that of investment. The profitable and secure investment of union health funds, as well as of union funds in general, constitutes a tremendous responsibility upon union leadership. Because persons directly in charge of union funds are free from the governmental restrictions to which most of the nonprofit fraternal organizations, savings banks, and insurance companies are subject, they have to use extreme prudence and care. Investment is a study in itself, and few of the union officials in charge of funds are trained in it. What may appear as a sound proposition to one man may be discarded by another for the sake of an additional fractional percent of interest. Most funds have met the problem by limiting investment to the purchase of Federal, State, and municipal bonds. This seems to be a fairly safe course to follow, and one which will not subject the administrator to criticism in the event the bonds drop in value. But even here there are elements of danger. Some municipalities and States represent a better risk than others. Standards should be set up as to types of investment. The question of maturities is similarly important. Portfolios must be so arranged that advantage is taken of changed financial conditions. It is a mistake to think that, once a Government bond is bought, it must be kept to maturity.

4. The complete segregation of health and welfare funds from the
general funds of the union is not only desirable but absolutely neces-
ary. It has already been noted that some unions were at times
ompelled to suspend or entirely liquidate their health and sick benefit
rograms because of industrial conflicts that completely drained their
esources. No union can consider itself forever immune from labor-
anagement clashes. Unless the health and welfare funds are prop-
rly segregated, there is danger that they may be used, directly or
directly, for general union activity. In this connection, there comes
mind an incident in the course of one of our perennial strikes in the
te 1920's. When I told the strike committee that the money to
hich reference was made was the property of the sick-benefit fund
e of the strike leaders told me, "If we don't win this strike, there'll
no union and no sick fund." To this I replied, "As long as there is
is sick fund, something will always be left of the union." Experience
t only in the ILGWU but in many other sections of the labor move-
nt has proved these words correct.

In the International Ladies' Garment Workers' Union and all its affiliates segregation of funds is an established and fixed policy. Its supreme governing body—the general executive board—has long ago laid down the law that in no instance and under no circumstances are funds to be intermingled.

Needless to say, trade-unions have entered the field of social welfare out of sheer necessity. The attitude of some employers with respect to the health and welfare of their workers and the past inadequacy of governmental plans left them no other course. However, it is hoped that the social security program of the Federal Government, which now offers only a limited form of protection, will eventually embrace all forms of sickness insurance and medical, mental, hospital, surgical, dental, and prenatal care. When this happens, some unions will gladly turn over their responsibilities to the Government and continue to pioneer in other fields of social reform and economic justice.

How well the Government will run this program, no one can tell. Some trade-unionists do not relish the idea of exposing their members to the potential red tape of bureaucratic management. When we reach that point, it may be well to rely upon the experience which the European trade-unionists had in this respect. In pre-Hitler Germany and Austria, as well as in the Scandanavian countries, welfare funds, under the name of "Arbeiter-Kranken und Sterbe-Kasse," functioned very satisfactorily on a tripartite basis—Government, industry, and labor. It may be that we can do the same, and with our American ingenuity, may be able to improve upon it. But I am not prepared to formulate any definite program of administration. We lack sufficient experience to come to definite conclusions. We should, however, endeavor to develop a workable and, above all, a humane approach to the problem. In the administration of health and welfare programs, we are constantly dealing with sick and disabled people. To restore them to health and at the same time help them retain their human dignity is a task worthy of our best talents and attention.

Letter of Transmittal

UNITED STATES DEPARTMENT OF LABOR,
BUREAU OF LABOR STATISTICS,
Washington, D. C., February 10, 1947.

The Secretary of Labor:

The attached directory of trade unions in the United States was prepared in response to the many requests received for information concerning labor organizations. It lists all national and international unions, various State labor bodies, and union research directors.

The directory was prepared in the Bureau's Industrial Relations Branch by John M. Brumm and Richard Shoemaker under the supervision of Nelson M. Bortz, chief of the Union and Management Research Division.

EWAN CLAGUE, *Commissioner.*

HON. L. B. SCHWELLENBACH,
Secretary of Labor.

Bulletin No. 901 of the
United States Bureau of Labor Statistics

Directory of Labor Unions in the United States

This directory of labor unions in the United States lists the addresses and principal officers of the American Federation of Labor and the Congress of Industrial Organizations, and of their affiliated unions and organizations. It also includes all national and international unions not affiliated with either the AFL or CIO which have come to the attention of the Department of Labor. A total of 105 AFL affiliates, 40 CIO affiliates and 52 independent or unaffiliated unions are listed. In addition, the directory contains a separate roster of union research directors.

Membership of national and international unions in the United States according to union statements and estimates based on union sources totaled approximately 15,000,000 at the beginning of 1947.

During 1946 a number of changes occurred in the affiliation and structure of American labor unions. These included the reaffiliation with the AFL in January 1946 of the United Mine Workers of America and the affiliation, also with the AFL during the year, of four other formerly independent unions—the National Association of Postal Supervisors, the Brotherhood of Railroad Signalmen of America, the Railroad Yardmasters of America and the Southern Tenant Farmers, Union, now known as the National Farm Labor Union.

The International Association of Machinists, suspended by the AFL in December 1945, and the Progressive Mine Workers of America, ssumed an independent or unaffiliated status. Two former AFL ffiliates, the International Union of United Brewery, Flour, Cereal nd Soft Drink Workers and the Amalgamated Lithographers of merica, received CIO charters in 1946.

One newly organized union, the Radio Directors Guild, was granted n AFL charter in September 1946, and the Air Line Dispatchers ssociation, formerly an AFL federal union, was chartered by the FL in February 1947. The United Public Workers of America CIO) was formed by the amalgamation of two former CIO unions, e United Federal Workers of America and the State, County and unicipal Workers of America.

Five small unions also became part of larger unions having jurisction in the same general field: The Air Line Communication nployees Association (Ind.) entered the American Communications sociation; the International Federation of Architects, Engineers, emists and Technicians (CIO) merged with the United Office and

Professional Workers of America (CIO); the United Financial Employees (Ind.) joined the Office Employees' International Union (AFL); the National Federation of Rural Letter Carriers merged with the National Association of Letter Carriers; and the United Licensed Officers of the U. S. A. (Ind.) became a part of the United Mine Workers of America, District 50 (AFL).

AMERICAN FEDERATION OF LABOR

901 Massachusetts Ave. NW
Washington 1, D. C.

President
WILLIAM GREEN

Secretary-Treasurer
GEORGE MEANY

Originally formed in 1881 as the Federation of Organized Trades and Labor Unions of the United States and Canada, the American Federation of Labor adopted its present name in 1886. In that year the Federation comprised 13 national and international unions with a total membership of approximately 150,000. Today the AFL has five major departments, 105 national and international unions and 50 State and Territorial branches. As of March 1947 the membership of the AFL, based on per capita tax payments received from affiliated unions, was in excess of 7,500,000.

Union Label Trades Department
901 Massachusetts Ave. NW
Washington 1, D. C.

President
Matthew Woll

Secretary-Treasurer
I. M. Ornburn

The function of the Union Label Trades Department is primarily to publicize the official emblems—union labels, shop cards, and service buttons—of 52 affiliated national and international unions. It also promotes the sale of union label goods and the patronage of union services.

CONGRESS OF INDUSTRIAL ORGANIZATIONS

718 Jackson Place NW
Washington 6, D. C.

President
PHILIP MURRAY

Secretary-Treasurer
JAMES B. CAREY

The Committee for Industrial Organizations (CIO) was formed in November 1935 to organize into unions all workers, irrespective of their skills, in certain mass production industries. The original committee was composed of 8 AFL unions. Differences between the AFL and its CIO-affiliated unions resulted in the latter's suspension and ultimate expulsion from the AFL. In 1938 the CIO adopted a constitution and its present name, the Congress of Industrial Organizations. The CIO currently has 40 national and international unions and 36 State branches and reports a membership of approximately 6,000,000 members.

INDEPENDENT (UNAFFILIATED) UNIONS

A number of unions are not affiliated with either the AFL or CIO and hence are commonly referred to as "unaffiliated" or "independent." The directory lists 52 independent unions known to the Bureau of Labor Statistics as having more than one local and holding collective bargaining agreements with more than one company.

At present, the largest and most widely known of the independent unions are the four train and engine service railroad brotherhoods with approximately 450,000 members, the International Association of Machinists, a former AFL affiliate, with 600,000 members, the National Federation of Telephone Workers numbering approximately 225,000 members, and the National Federation of Federal Employees reporting a total membership of 88,000. At the beginning of 1947, total independent union membership in the United States was estimated at slightly more than 1,750,000.

RAILWAY LABOR EXECUTIVES ASSOCIATION

10 Independence Ave. SW
Washington 4, D. C.

Chairman
T. C. CASHEN

Executive Secretary-Treasurer
A. E. LYON

The Railway Labor Executives Association, organized in 1926, is "an unincorporated and voluntary association of the chief executive officers of the following standard railway labor organizations representing substantially all organized railway workers in the United States and Canada:"

Brotherhood of Locomotive Firemen and Enginemen (Ind.)
Order of Railway Conductors of America (Ind.)
Switchmen's Union of North America (AFL)
Railroad Yardmasters of America (AFL)
Order of Railroad Telegraphers (AFL)
American Train Dispatchers' Association (Ind.)
Railway Employes' Department (AFL)
International Association of Machinists (Ind.)
International Brotherhood of Boilermakers, Iron Ship Builders and Helpers of America (AFL)
International Brotherhood of Blacksmiths, Drop Forgers and Helpers (AFL)
Sheet Metal Workers' International Association (AFL)
International Brotherhood of Electrical Workers (AFL)
Brotherhood Railway Carmen of America (AFL)
International Brotherhood of Firemen and Oilers (AFL)
Brotherhood of Railway and Steamship Clerks, Freight Handlers, Express and Station Employes (AFL)
Brotherhood of Maintenance of Way Employes (AFL)
Brotherhood of Railroad Signalmen of America (AFL)
National Organization Masters, Mates and Pilots of America (AFL)
National Marine Engineers' Beneficial Association (CIO)
International Longshoremen's Association (AFL)
Hotel and Restaurant Employes' International Alliance and Bartenders' International League of America (AFL)

Washington 25, D. C. - Price 20 cents

LETTER OF TRANSMITTAL

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., June 1, 1947.

The Secretary of Labor:

I have the honor to transmit herewith the report on a study of employment outlook in printing occupations. This is one of a series of occupational studies, conducted in the Bureau's Occupational Outlook Division for use in vocational counseling of veterans, young people in school, and others interested in choosing a field of work.

The report was prepared by Samuel Vernoff, under the supervision of Helen Wood. Doris M. Graham performed the library research and assisted in the preparation of the report. Sections on earnings were prepared with the help of Donald H. Gerrish, of the Bureau's Wage Analysis Branch, and are based largely on data collected by that Branch. The Bureau wishes to acknowledge the generous assistance received from the Printing Industries of America (Fred J. Hartman, educational director), the Graphic Arts Association of Washington, D. C. (George I. Mallonee, executive secretary), other trade associations, and the Joint Lithographic Advisory Council; from officials of many unions; from members of the staffs of the Government Printing Office, Bureau of Engraving and Printing, U. S. Employment Service, and other Government agencies.

Ewan Clague, *Commissioner of Labor Statistics.*

Hon. L. B. Schwellenbach,

Secretary of Labor.

EMPLOYMENT OUTLOOK IN PRINTING OCCUPATIONS

Introduction

Printing is an art, a great industry, and one of
ur chief means of communication. Developed in
ermany about five hundred years ago, printing
ade possible the extension of education. As
rinted books and pamphlets multiplied and news-
apers began to be published, they played a great
art in spreading ideas, influencing public opinion,
d aiding the people to obtain a voice in govern-
ent. Their contribution to the growth of democ-
cy was so fundamental that freedom of the press
s one of the basic rights incorporated in the first
endment to the United States Constitution.

Over 600,000 men and women made their living in the printing industries in 1946. More workers were employed in printing than in such large manufacturing industries as furniture, leather, and rubber or such important public utilities as telephone and electric-light companies. Printing is especially important as a field of employment for skilled men, affording opportunities in many different skilled occupations and, as a rule, paying better-than-average wages. Jobs are to be found in all parts of the country, in small towns as well as big cities. Many printing craftsmen are in business for themselves.

The Printing Industries

rinting plants supply us with a great variety
roducts—ranging from newspapers to greet-
ards, from books to advertising circulars, from
er money to labels.

he establishments engaged in newspaper print-
and publishing make up by far the largest
ting industry in terms of employment (see
t 1).[1] More than a third of the people work-
n the printing industries in 1939 were in news-
r shops. Furthermore, the dollar value of
produced in newspaper plants was much
er than for that of the products of any other
ing industry.

eral commercial or job printing is the second
st printing industry. There are many more
ercial shops than newspaper plants, but the
ge job shop is so small that commercial
ng as a whole has both fewer employees and
ller dollar value of output than newspaper
ng.

Periodicals and books are the next largest printing industries. Smaller industries are engaged mainly in producing lithographed items of various types, greeting cards, or gravure products, or in doing bookbinding and other bindery work. The so-called service industries for the printing trades do mainly typesetting, photoengraving, or other work for printing shops. In addition, many printing and bindery workers are employed by government agencies, libraries, and manufacturers and other firms doing some printing in connection with a business of another type. The largest printing plant in the world is the United States Government Printing Office in Washington, D. C.

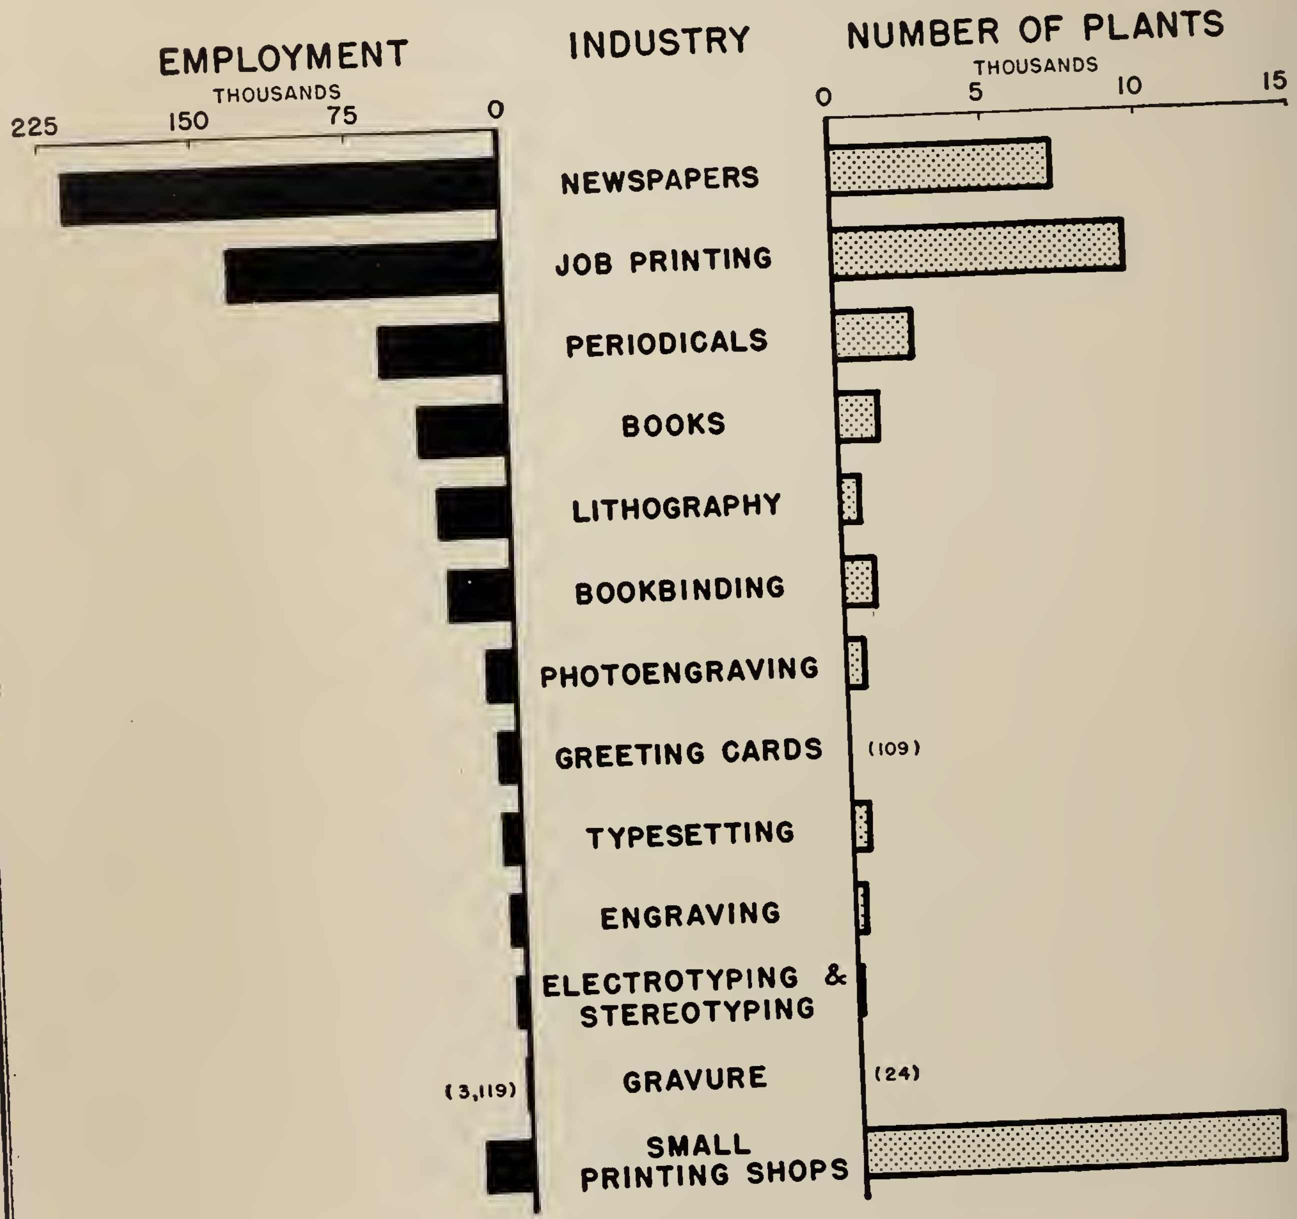
---

[1] The classification of printing plants in this bulletin is that used by the Census of Manufactures. It is discussed in the appendix, which also gives figures on the number of establishments, value of products, and number of proprietors and employees in each industry (see p. 30).

CHART 1

NEWSPAPER AND JOB SHOPS EMPLOY MOST PRINTING WORKERS

NUMBERS EMPLOYED AND NUMBERS OF PLANTS IN PRINTING AND ALLIED INDUSTRIES, 1939



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Source: CENSUS OF MANUFACTURES AND CENSUS OF BUSINESS
REFER TO APPENDIX FOR FIGURES AND EXPLANATIONS

great—about 39,000 in 1939, not counting shops outside the printing industries. Only one group of manufacturing industries (food processing) included more establishments than this. Some printing plants are million-dollar enterprises with hundreds of employees, but a great number of printing plants are very small. In 1939, there were about 14,000 shops (over a third of the total) with an output valued at less than $5,000 a year and often with only 1 worker, the owner himself.

Almost every small town has a printing shop of some kind—frequently a small newspaper plant which also handles any job printing needed in the community. However, a large part of the country's printing is done in 10 industrial cen-

geles, San Francisco, Detroit, Cleveland, St. Louis, Cincinnati, and Minneapolis-St. Paul. In 1939, about half of all employees in the printing and allied industries were in these centers. In job and periodical printing, and some of the smaller industries, the proportion of employees in the 10 major centers was even greater. The proportion was, however, much less (only 32 percent) in the newspaper industry, since there are a great many small local newspapers scattered throughout the country. In addition, some large plants are located in other centers, including Boston, Cambridge, Clinton, and Norwood, Mass.; Albany and Garden City, N. Y.; Rahway, N. J.; Richmond, Va.; Hammond, Ind.; and Kingsport, Tenn.

The Methods of Printing

The three main methods of printing are letterpress, lithography, and gravure.

In letterpress (or relief) printing, the letters nd designs to be reproduced are raised above the onprinting areas of the type or the press plate. Vhen the actual printing is done, ink is applied nly to the letters and designs, usually by means f an inking roller.

In lithography (or offset printing), the plate is nooth or nearly so, with both the image and non-nage areas on the same level, instead of on dif-erent levels as in letterpress and gravure work. ithography makes use of the principle that grease d water repel each other. The image areas of e plate are coated with a greasy substance to hich the greasy printing ink will adhere. On e press, the plate is moistened with water before ch inking, with the result that only the image eas take up the greasy ink from the inking roller.

In gravure (or intaglio) work, the relation be-een the printing and nonprinting areas of the te is opposite to that in letterpress. The letters l designs to be printed are cut or etched into the te and are below the nonprinting surface. Ink to be applied to the entire plate, but the sur-e is then wiped or scraped, leaving ink only he depressions. In printing, suction is created, ch lifts the ink out onto the paper.

etterpress is the oldest and by far the most mon printing process. Practically all newspapers, most books and magazines, and most commercial jobs are printed by this method. The work done by photoengraving shops (which make plates for use in relief printing of illustrations and other copy that cannot be set up in type) and by stereotyping and electrotyping shops (which produce metal duplicates of type forms and photoengravings, for use as press plates) is also part of letterpress printing.

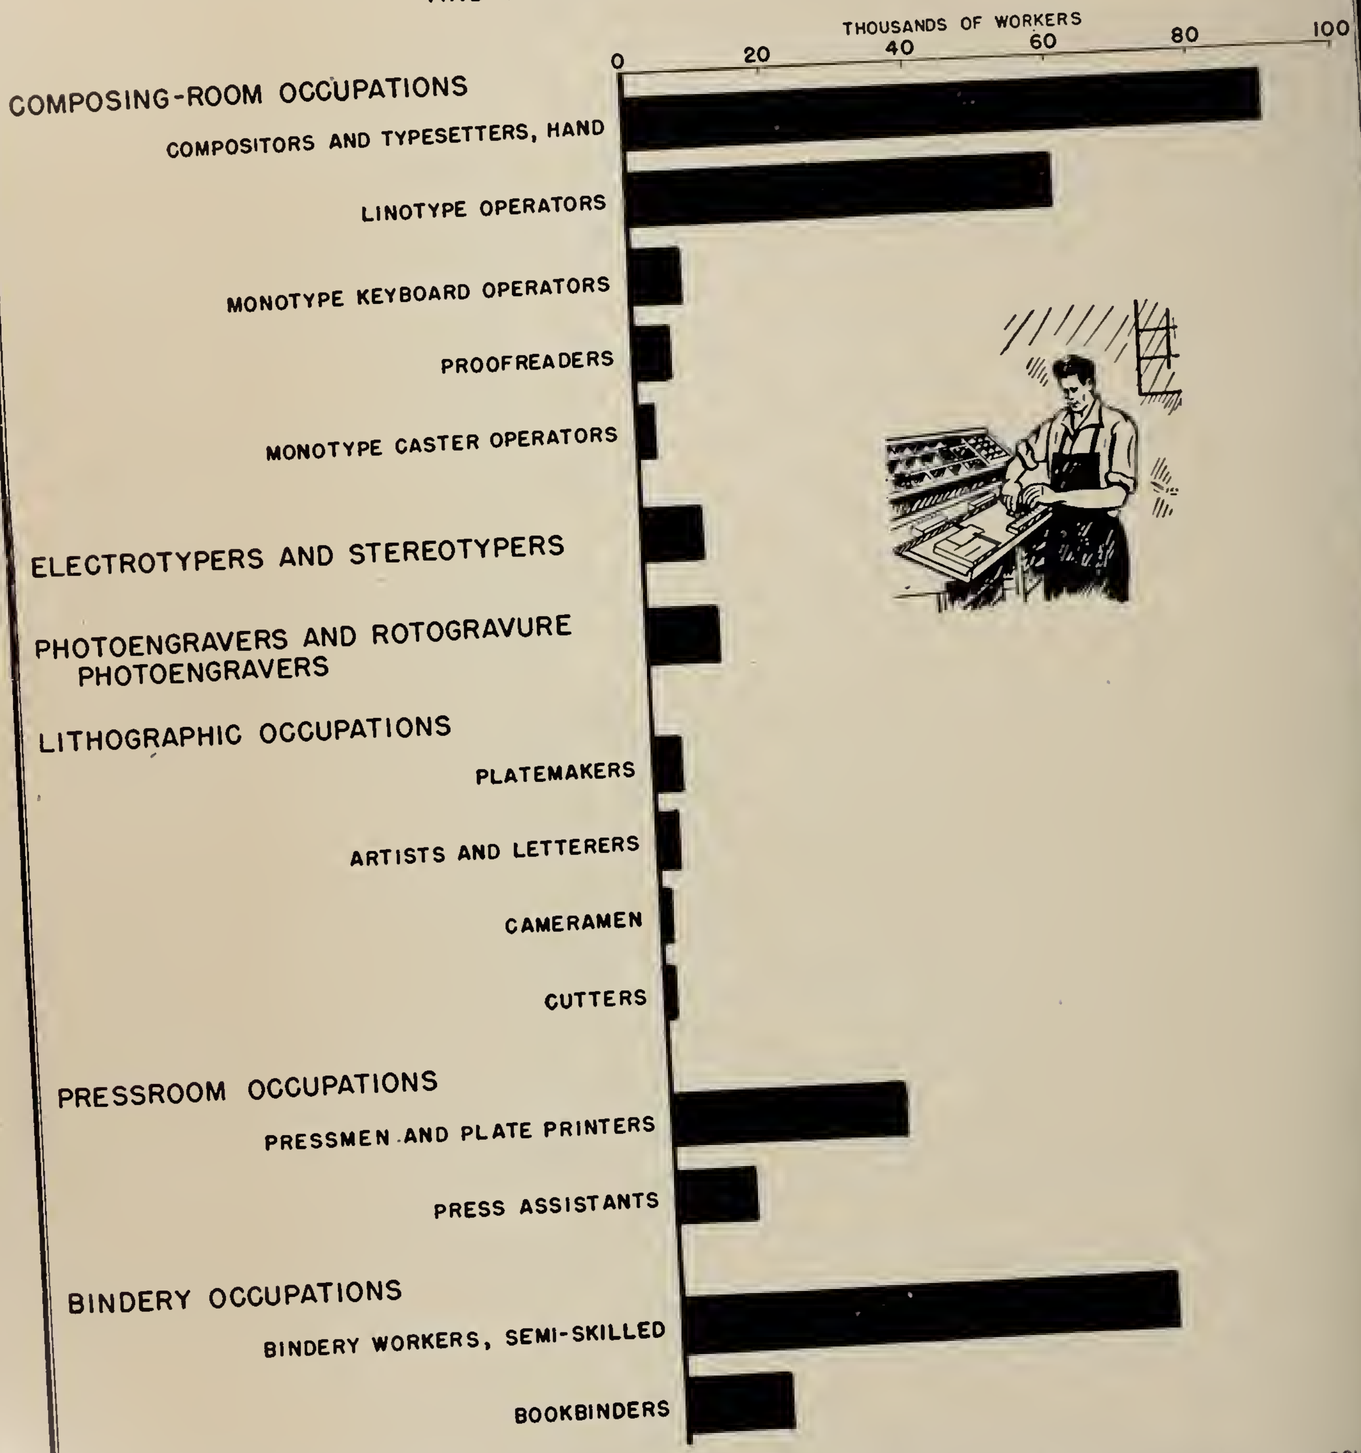
Lithography, though still much less common than letterpress work, is the most rapidly growing method of reproduction. Practically all items printed by the relief process are also produced by lithography—including, for example, books, calendars, maps, posters, labels, office forms, sheet music, and even newspapers. Almost all printing on metal and much of the printing on rough paper is done by this method.

Gravure printing, the least common process, is of two main types: rotogravure (in which press plates are made from pictures by a method based on photography) and hand or machine engraving. The beautiful picture supplements of some Sunday newspapers are the best known rotogravure products, but some magazine and other pictures are printed by this means. The process is used also in some printing on metal and metal foil. Hand or machine engraving is used in making engraved stationery, greeting cards, and similar products.

CHART 2

HAND COMPOSITORS AND LINOTYPE OPERATORS ARE LARGEST SKILLED TRADES

EMPLOYMENT IN THE IMPORTANT SKILLED AND SEMI-SKILLED PRINTING AND BINDERY OCCUPATIONS, 1940



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

BASED ON 1940 CENSUS OF POPULATION AND OTHER SOURCES

The all-round printer, skilled in typesetting and also in operating a press, was the typical printing worker up to the closing years of the nineteenth century. Some craftsmen who are adept in both these kinds of work are still employed in small newspaper and job shops. In the printing industries as a whole, they are, however, greatly outnumbered by specialized craftsmen and semiskilled employees.

The largest group of skilled and semiskilled workers are in the composing room, the department responsible for typesetting. Other major groups are the printing pressmen and their assistants, photoengravers and rotogravure photoengravers, electrotypers and sterotypers, lithographic workers, and bookbinders and bindery vorkers. Chart 2 shows the number of people mployed in 1940 in each of the main occupations n these categories.

Besides the occupations shown in chart 2, there re many other small groups of skilled or semi- killed printing workers. In some plants, espe- ially in the newspaper industry, the composing- oom work force includes Ludlow operators, who in a typecasting machine known as the Ludlow ypograph. Big composing rooms nearly always nploy one or more "stonemen," who place the iges of type in the large type forms in which they ave the department. Another small group of orkers found in large plants are the mechanics io specialize in repairing and adjusting typesetting machines, printing presses, or bindery machines. Steel- and copper-plate engravers, on the other hand, work mainly in small engraving shops. They cut or etch lettering and designs in the plates, by hand or machine.

Most of the occupations indicated in the chart and the preceding paragraph are skilled jobs. The main exceptions are press assistants and bindery workers whose jobs are semiskilled, as are those of many monotype caster operators and some lithographic workers. Proofreaders in nonunion shops are sometimes classed as clerical employees.

In skilled occupations practically all the workers are men. However, many of the semiskilled workers, especially in binderies, are women. Negroes are rarely employed in skilled jobs, except in shops which print newspapers or other items for the Negro community. A greater number are employed in semiskilled occupations.

To complete the picture of the printing work force, the professional, administrative, clerical, and unskilled employees of printing plants should be mentioned. The chief professional workers are the reporting and editorial staffs of newspapers and other houses that do their own publishing. In addition, all sizable plants have executives, estimators, salesmen, stenographers and other clerks, and laborers of various types. These employees usually have duties much like those of comparable personnel in other industries.

Employment Prospects

There will be many thousands of job openings printing during the next few years, including uch larger number of training opportunities n usual.

t the end of World War II there were marked or shortages in almost all occupations. How- r, before the war (in 1940), about 1 out of ry 10 skilled and semiskilled printing workers unemployed. This situation quickly changed r Pearl Harbor, when many workers went into armed forces and into war industries. In ad- on, there were, of course, some retirements and hs. Replacements could not be obtained in cient numbers, because of the Nation-wide labor shortage. As would be expected, it was particularly hard to recruit young men for training.

Since the end of the war, employers have been rehiring former employees and have taken on a good many new trainees. The number of production workers employed has risen steadily (by about a fourth between September 1945 and December 1946 in the printing industries as a whole). There are still shortages of journeymen in many parts of the country, however. The outlook is for greater and greater activity and employment in all branches of printing, at least during the next few years, because of growing demands for printed products such as advertising materials and text-availability of new machinery and supplies, and other factors. Unusually large numbers of job openings owing to retirements and deaths may also be expected for a while, because of the postponement of retirements during and since the war and the fact that the average age of journeymen is therefore higher than before. For all these reasons, it will generally be easy for skilled workers to get jobs during the years immediately ahead. In addition, there should continue to be a good many training opportunities, although the numbers of apprentices who may be employed at any time are limited by the ratios of apprentices to journeymen established by union agreements. Veterans with related civilian or military training and experience will generally be given preference for apprentice positions. Some of them should be able to obtain advanced status as learners, instead of being hired as beginners.

Openings for newcomers will probably be fewer hiring may already have been reached. However, workers who now have jobs in the printing field or who obtain them "while the getting is good" are likely to be able to hold them indefinitely. Printing employment tends to be less affected by declines in general business activity than employment in manufacturing as a whole. Moreover, the long-run trend in employment is upward in most printing occupations.

In general, the largest number of job openings will be in the printing centers previously mentioned (p. 3). Opportunities will, however, be more scattered in some branches of printing than in others. They will, for example, be more widespread in newspaper than in job printing; but in lithography, they will be concentrated in the major centers to a greater extent than in either of these industries. In all branches of printing, competition for jobs is likely to be keenest in largest cities.

Earnings

Earnings tend to be higher in printing than in many other industries, owing to the large number of skilled workers employed, the strong influence of the printing unions, and other factors. In 1940, wage earners in book and job shops averaged 81 cents an hour; newspaper and periodical plants, $1.03. By comparison, the average for all manufacturing was only 66 cents an hour. In no other manufacturing industry for which information was available were average earnings as high as in newspaper and periodical plants. This was still true during 1946, when earnings averaged $1.21 an hour in book and job shops and $1.46 in newspapers and periodicals, compared with $1.08 in all manufacturing.

What an individual printing worker can expect to make varies greatly from one occupation to another, as well as from city to city, and in other ways. The best source of information on wages in different occupations are union wage scales. These scales are the minimum rates paid under collective-bargaining agreements and are usually uniform for each occupation in a given locality. They are, in general, representative of wage rates in skilled and semiskilled printing trades, which are all highly organized.[2]

In July 1946, union wage scales averaged about $1.58 an hour. For the skilled workers, rates were generally between $1.30 and $2.00 an hour; for the others, they were usually between 70 cents and $1.30. Since July 1946, wage scales have increased further in many large cities. Chart 3 shows the average wage rates for most of the major trades. Later sections of this bulletin give additional information on wages in these and other occupations. A detailed table on union wage rates in different cities is included in the appendix (p. 31).

The wage scales that have been cited are the basic rates received by employees on day shifts. In most printing plants, as in many other manufacturing establishments, workers are paid time and a half for overtime work not only above a standard number of hours a week but also above 8 hours a day. The standard workweek is usuall 37½ hours in newspaper plants. In other print ing shops, it is usually 40 hours. Work on Sun days and holidays is customarily paid for at time

---

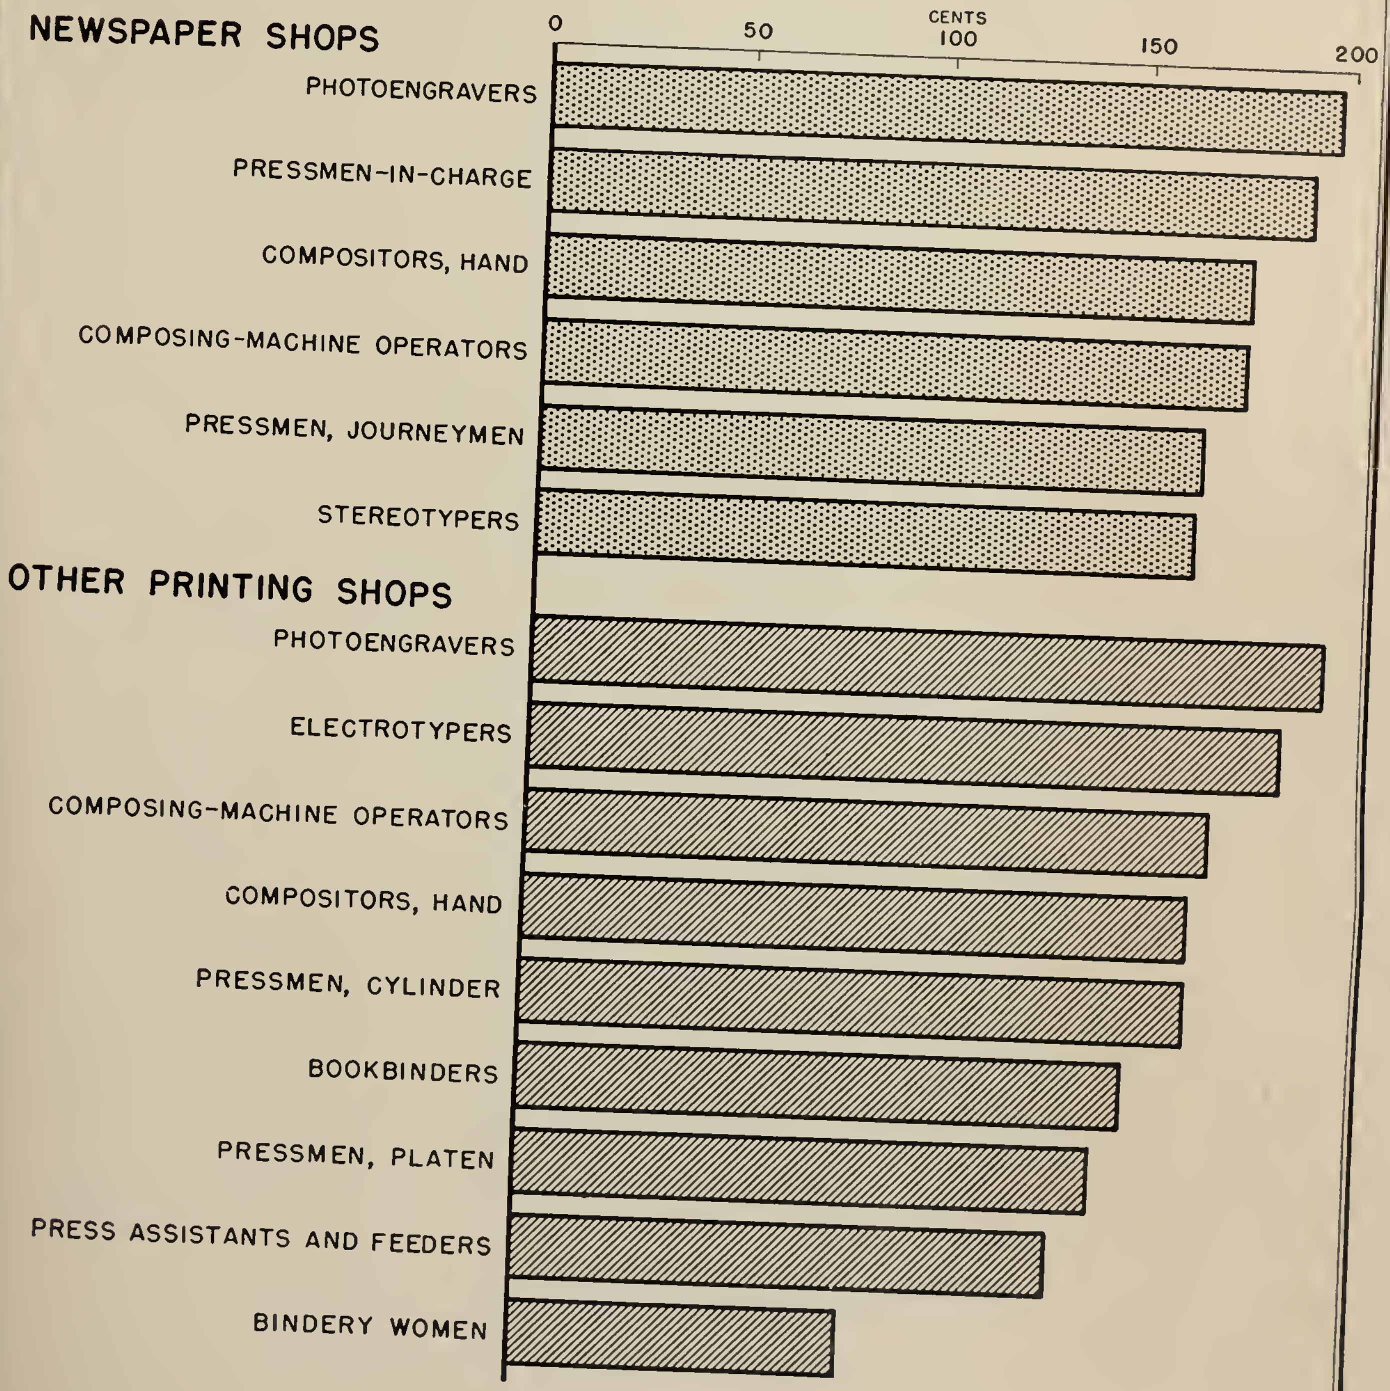
[2] Union wage scales are not available for unskilled job Moreover, they do not include premium pay for overtime or oth special payments or bonuses. As a result, they are not co parable with the average earnings figures given in the precedi paragraph, which include all types of wage payments and cov all wage earners.

CHART 3

WAGE RATES IN PRINTING TRADES

AVERAGE UNION RATES PER HOUR IN NEWSPAPER AND OTHER PRINTING PLANTS, FOR SELECTED OCCUPATIONS

JULY 1, 1946



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

of printing. In newspaper plants, the standard workweek often includes Sundays and work has to go on as usual on holidays; however, time and a half or double time is paid for these days only when they are not part of the employee's regular shift. Night-shift workers in union shops generally receive about $5 extra for a 37½- or 40-hour week. There are many other types of provisions for overtime and special rates of pay.

How much workers earn during a year depends not only on their rates of pay but also on how are fortunate in having steadier employment and earnings than those in many other industries. Earnings tend to be especially steady in newspaper work.

Paid vacations are called for by most wage agreements. The majority of union workers receive 2 weeks' vacation with pay after 1 year of employment. In addition, the printing unions are noted for welfare provisions for their members: for example, pensions, sanitarium facilities, and educational programs.

Labor Organization

Workers seeking jobs in printing trades will find that the printing unions not only influence wages and working conditions but often have a strong voice in determining hiring policies. Many plants are covered by closed-shop agreements, under which all workers in specified trades have to belong to the appropriate union. Union members are also often employed in plants having no union contracts.

There are six major unions of printing workers. Five are craft unions affiliated with the American Federation of Labor—the International Typographical Union, International Printing Pressmen's and Assistants' Union of North America, International Photo-Engravers' Union of North America, International Stereotypers' and Electrotypers' Union, and the International Brotherhood of Bookbinders. The sixth, the Amalgamated Lithographers of America, organizes workers in all lithographic occupations. It is a member of the Congress of Industrial Organizations.

Most typesetters and other composing-room workers are represented by the International Typographical Union. In newspaper and job printing, either shop foremen who are themselves union men or the union shop chairmen usually do the hiring, disciplining, and firing of composing-room employees, in accordance with union rules. Pressroom workers, too, are usually covered by union agreements. Practically all the letterpress and rotogravure pressmen who are organized belong to the International Printing Pressmen and Assistants' Union. The large majority of lithographic and offset pressmen, as of other lithographic workers, are in the Amalgamated Lithographers of America.

Photoengravers are almost completely organized by the International Photo-Engravers' Union of North America. The proportion of stereotypers and electrotypers unionized by the International Stereotypers' and Electrotypers' Union is likewise extremely high.

Although employees in binderies are not so strongly organized as the groups discussed in the last two paragraphs, many skilled bookbinders and other bindery workers are represented by the International Brotherhood of Bookbinders. Th proportion of workers belonging to this union i higher among journeymen than among less-skille employees.

How To Enter Printing Occupations

Apprenticeship is the accepted way of entering skilled printing occupations. With very rare exceptions, it is the only means by which one may qualify as a journeyman in a union shop.

Printing apprenticeships usually last from 4 to 6 years, depending on the occupation and whether the shop is union or nonunion. The training program covers all phases of the particular trade an almost always includes classes in related technic subjects as well as training on the job. When a apprentice starts out, he is usually paid 30 or percent of the wage rate for journeymen. Ho ever, his pay is increased once or twice a year, unt in the final year or half-year of training, he

Men who have had some experience in the trade, in either civilian life or in the armed forces, can often obtain credit for this. They will then start out at a wage above the beginning apprentice rate, and the length of time before they become journeymen will be reduced. Veterans who qualify under the GI bill of rights may also receive allowances from the Federal Government during part or all of the training period.

To be eligible for apprenticeship, applicants are generally required to be 18 (though sometimes only 17) years of age and not over 30. A physical examination is usually given to find out whether the applicant is free from communicable diseases, has eyesight adequate for the particular occupaion, and is in good enough physical condition to lo the work which will be involved in his job. Exceptional physical strength is rarely required. Moreover, printing is, on the whole, a relatively good field of employment for handicapped people. A considerable number of workers with speech or earing defects—even some who are totally deaf—re employed, particularly as linotypists and comositors. Men who have lost 1 or both legs or do ot have the use of all 10 fingers have proved satisctory in some composing-room occupations. In eneral, success in a job depends on the individual's ility to do the work and to adjust himself to ecific working conditions. Therefore, handipped people should not consider themselves aumatically disqualified for employment in the dustry but should seek competent professional vice.

Education is another factor which employers nsider in selecting apprentices. High-school aduation is usually required and always prered. A thorough knowledge of spelling, punction, and grammar is essential for most trades.

desirable. If a person had printing courses in high school (thousands of junior and senior high schools offer such courses as a part of their industrial arts programs), this will also be greatly in his favor. In addition, courses in art, such as drawing, design, color, and lettering, are helpful for many kinds of printing work.

Information on opportunities for apprenticeship or other types of printing employment in a particular locality may be obtained from several different sources. Applicants may go to the nearest office of their State employment service, affiliated with the U. S. Employment Service, or to any printing plants in the neighborhood (the addresses can be obtained from the classified section of the local telephone directory). Local unions and local employer associations can be of great assistance. If none are listed in the telephone directory, an applicant may write to the national headquarters of these organizations (the addresses are given in the appendix, p. 33) and ask them to refer the letters to their nearest branches. Editors of hometown newspapers can also give valuable information and advice. Veterans may find out about opportunities for on-the-job training and other questions at veterans' information centers or offices of the Veterans Administration or from veterans' representatives in offices of their State employment service.

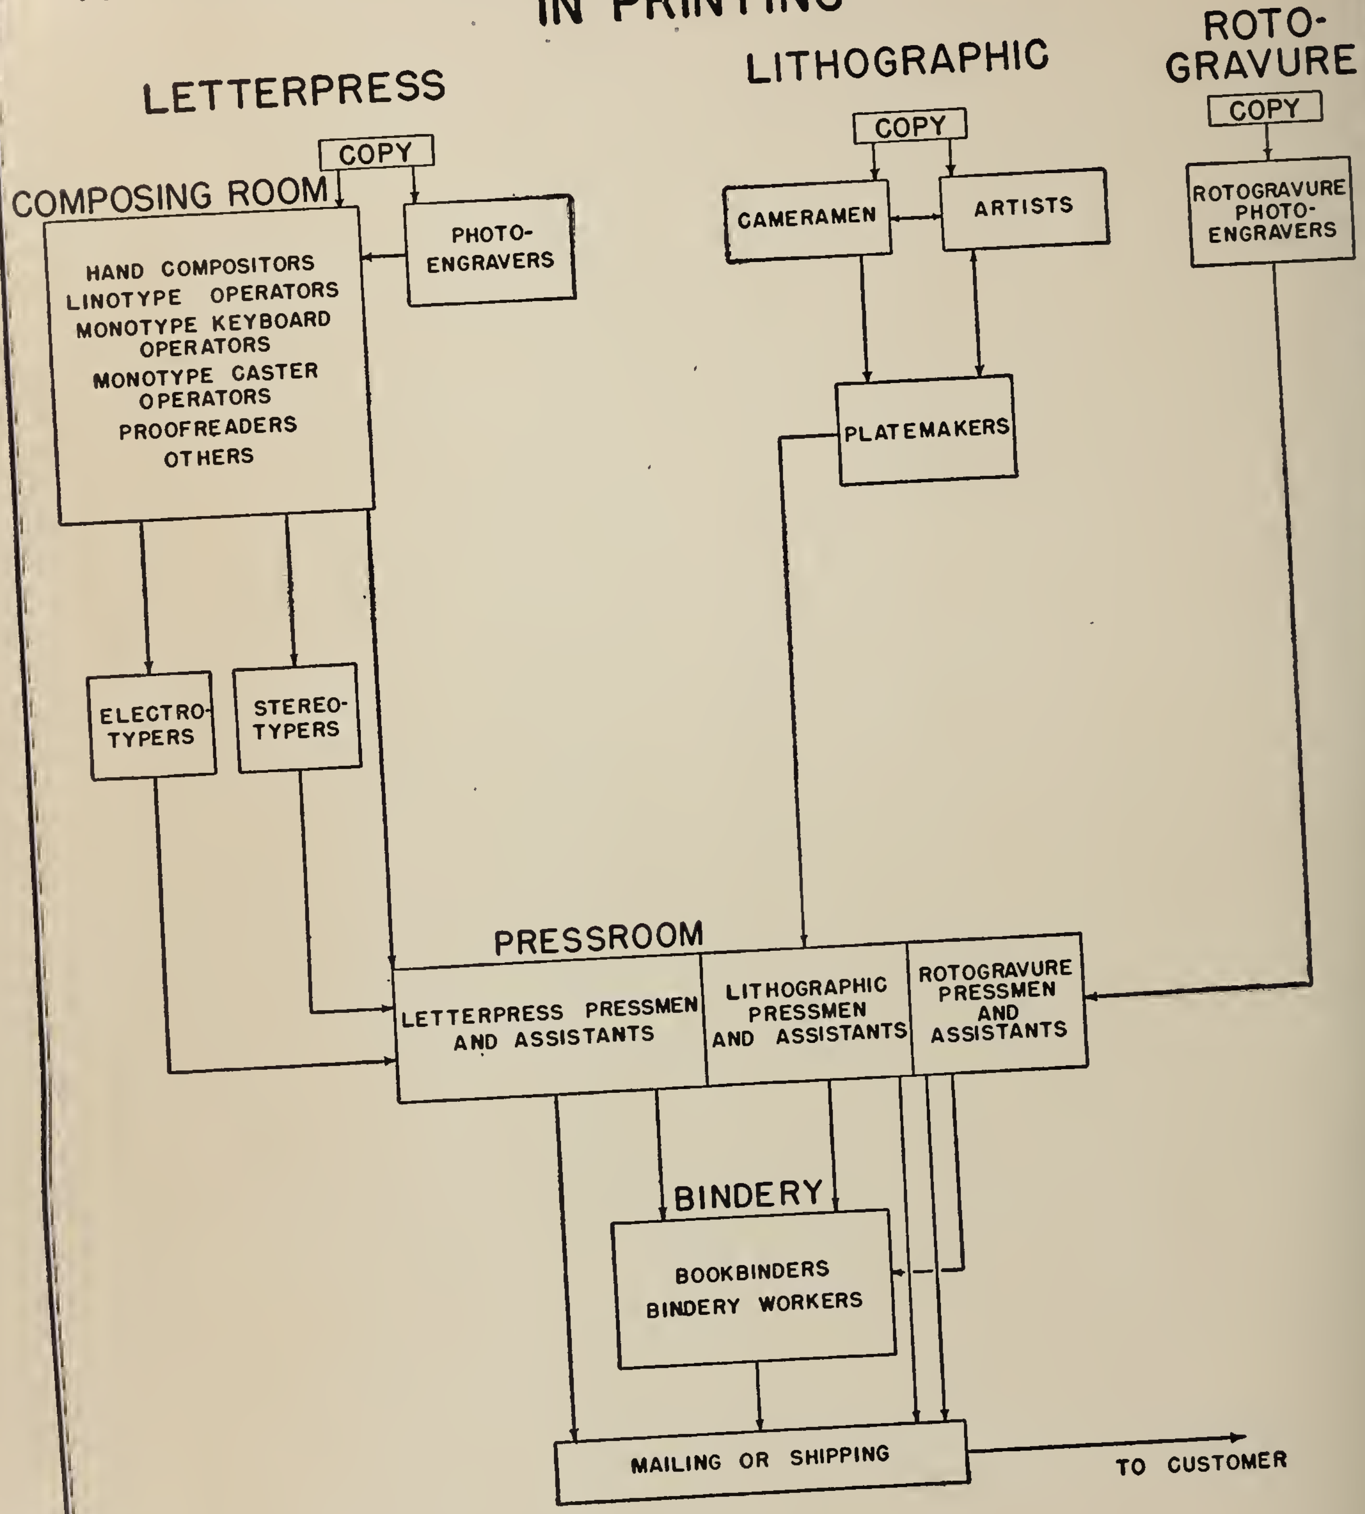
The employment outlook in many important skilled and semiskilled occupations is discussed in the following sections of this bulletin, which also presents information on the nature of the work, qualifications for employment, and earnings in each trade.[3]

---

[3] A list of books and pamphlets, which contain additional information on printing occupations and are available in many public libraries, is given in the appendix (p. 34).

CHART 4

A GENERAL PICTURE OF THE FLOW OF WORK IN PRINTING



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Composing-Room Occupations

Copy to be printed by the letterpress process starts its trip through a printing plant in the composing room, as shown in chart 4. There the type s set and assembled in type forms, ready for the pressroom—or for electrotyping or stereotyping, f printing is to be done from press plates instead of directly from the type forms.

Hand Compositors and Typesetters

The oldest and largest composing-room occupa- ion is that of hand compositor or typesetter. About 90,000 of these journeymen printers were mployed in 1940. In some small shops, all the ype is still set by hand. This involves setting ach line of type in a “composing stick”—letter y letter and line by line (as shown in the accom- anying picture)—and, when the stick is full, iding the completed lines onto a shallow metal ay or “galley.” In many shops, all “straight atter” (such as you are now reading) is set by achine, but hand compositors are still needed to t some of the type required for headlines, titles, d other special work, and to assemble the ma- ine- and hand-set type. Taking proofs of type at has been set (that is, printing a few copies on proof press), checking the proofs against the iginal copy, and correcting errors in typesetting e among the other duties sometimes performed compositors, particularly in small shops. These rkers may be responsible also for page make-up rranging type and any needed engravings into ges) and for locking the completed pages into rms. In large plants, however, page make-up usually done by special “make-up men,” chosen m among the compositors, and the type forms generally locked up by “stonemen.”

ll the major branches of printing—newspaper, , book, and periodical—employ large numbers hand compositors. Smaller numbers work in er kinds of printing shops or in service shops ng typesetting on contract for printing estab- ments. A good many men in the occupation e their own small job or service shops.

Qualifications for Employment

A 6-year apprenticeship is usually required for employment as a journeyman compositor or typesetter. In union shops, apprenticeship is always of this length, except in the case of some veterans with military experience related to printing and apprentices for whom shop foremen recommend shorter training periods in recognition of their outstanding abilities. The apprenticeship includes a considerable amount of classroom and correspondence study. Printed manuals of instruction have been prepared by the International Typographical Union and the Printing Industry of America; these are used not only in apprenticeship programs but also in vocational schools.

Besides having the educational qualifications needed for all skilled printing occupations (p. 9), a compositor should be good in arithmetic, so that he can calculate spacing of type on pages. A knowledge of English is especially important in this occupation, since the worker should be able to catch errors in copy before setting type. Imagination and artistic ability in planning page lay-outs are assets which may help him to advance to lay-out work or make a success in business for himself.

For a job in this trade, the worker should be in good enough physical condition to enable him to be on his feet 8 hours a day and move around considerably. He should also be able to use hands, arms, and eyes constantly.

Employment Prospects

Employment opportunities for journeymen compositors are expected to be good in most parts of the country during the next few years. In some areas, however, an oversupply of craftsmen developed after VJ-day, and experienced men are still available for employment in a few localities. For inexperienced men, there will be large numbers of openings as trainees for several years. After that, training opportunities will become

Courtesy of U. S. Government Printing Office, Washington, D. C.

Hand compositor setting type in a composing stick.

much fewer. Contrary to the upward trend in most printing occupations, employment in this field will no doubt tend to decrease (as it was doing before the war) owing to continued advances in machine typesetting and to other factors. The decline will be slow and will probably not involve many lay-offs. Men in the occupation, including those who enter during the current period of expansion, should have a good chance of holding their jobs indefinitely, especially if they have machine (linotype or monotype) as well as hand skills.

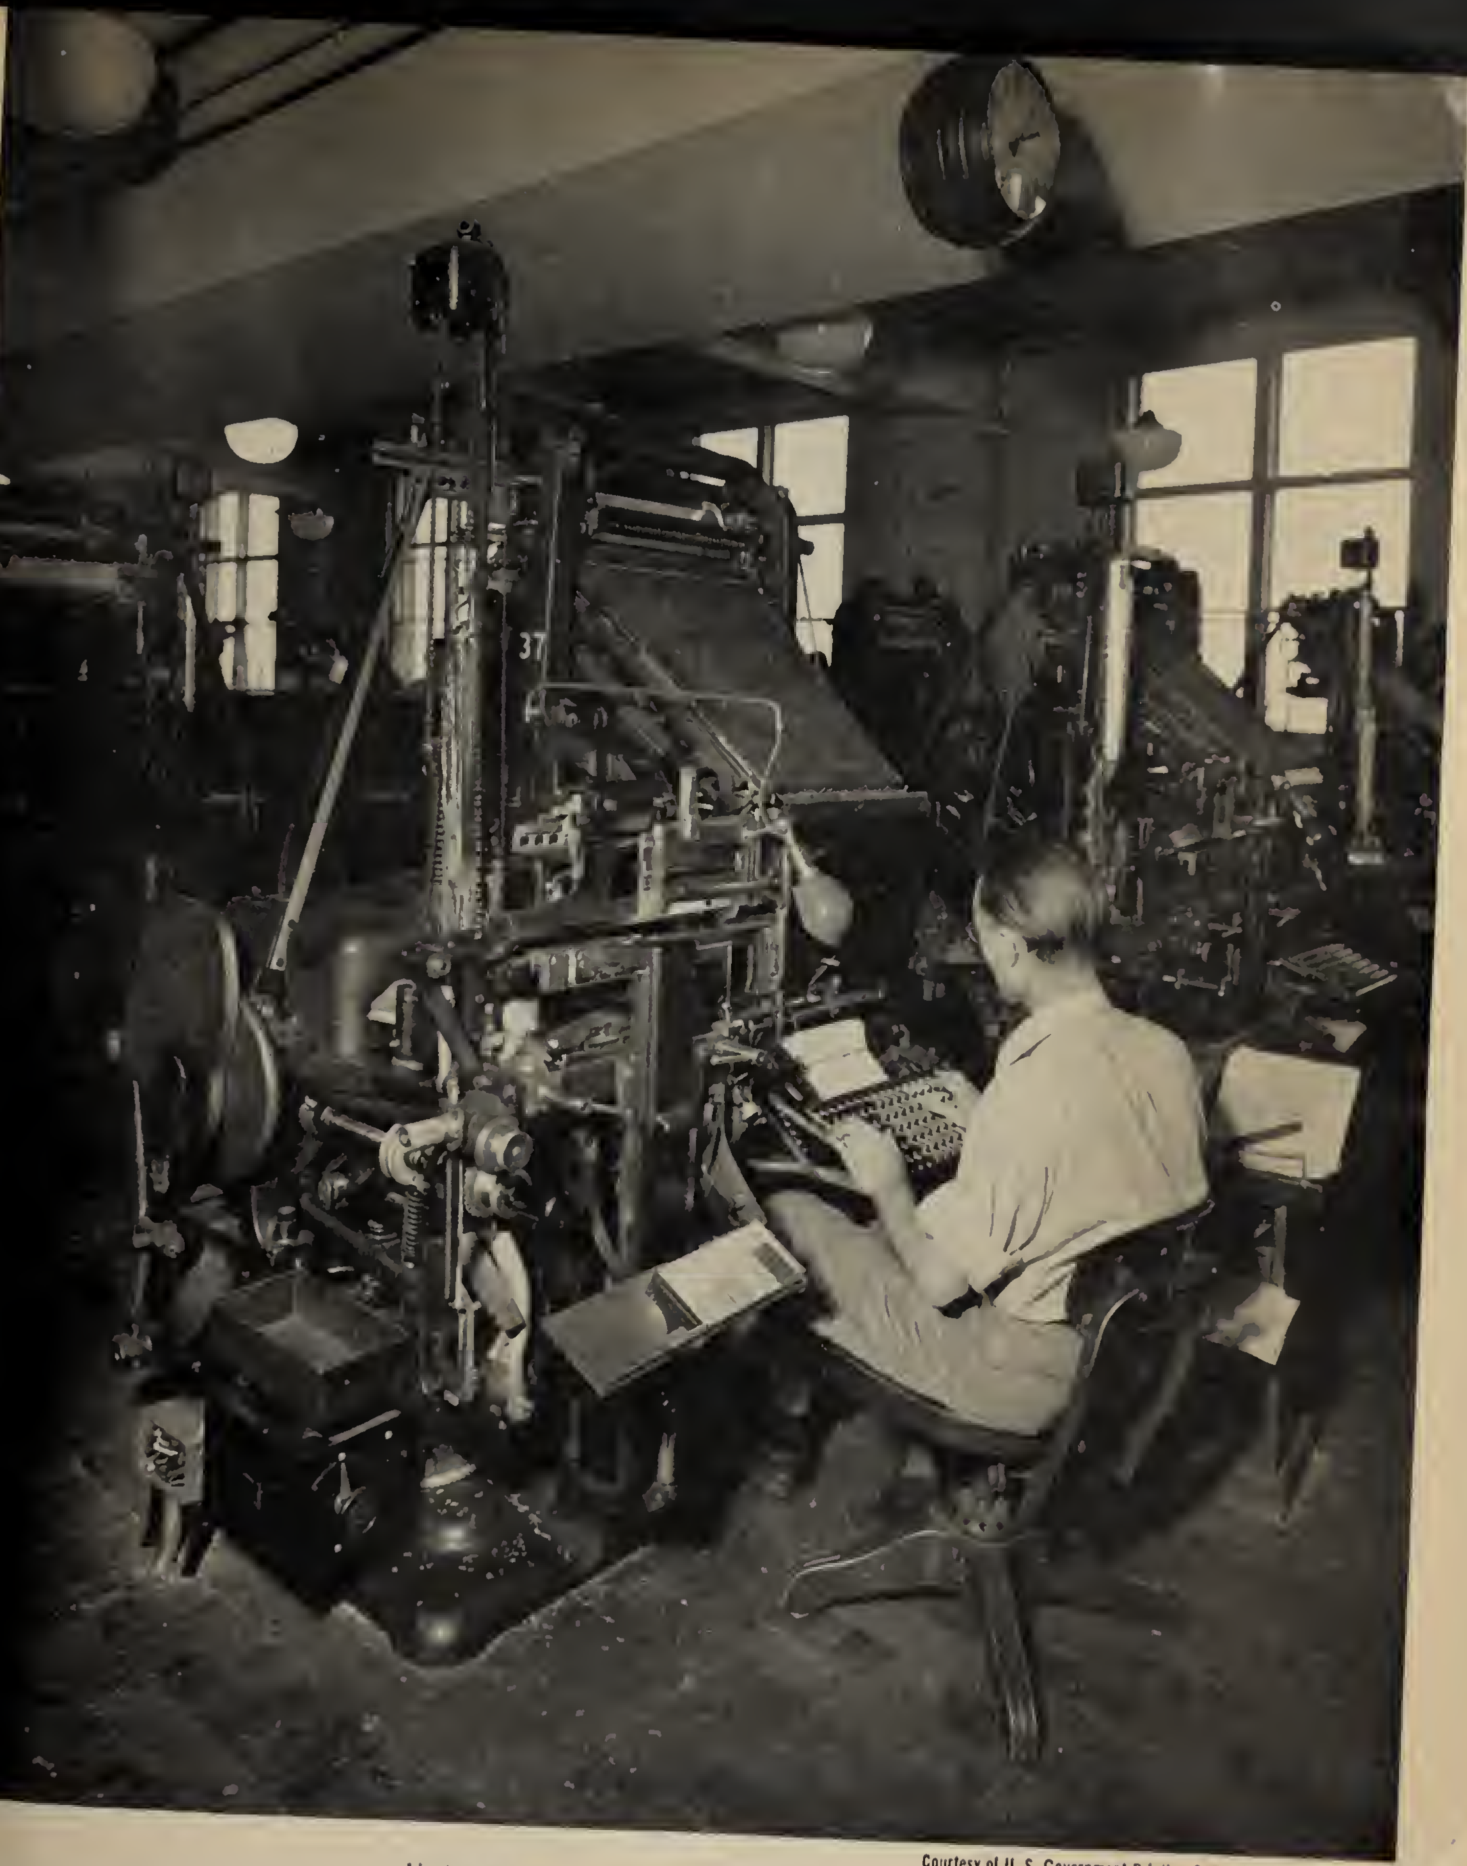
For years there have been so many small general printing shops that competition for business has been keen in most parts of the country and earnings have often been very inadequate. Some veterans and others wishing to go into business for themselves may, however, find opportunities during the next few years, as machinery and paper become more readily available. Generally, those with good all-round civilian experience will have the best chance of success. Men with composing-room skills plus supervisory and managerial abilities will also find some immediate openings in salaried positions with large and well-established firms and, in general, good opportunity for advancement to such positions.

Hand compositors are among the better-paid printing trades workers. Union wage rates in this trade averaged $1.85 an hour in newspaper shops and $1.65 an hour in other shops in July 1946. Both these averages were well above the average union scale for all printing trades ($1.58 an hour). Wage scales for compositors in newspaper plants ranged from $1.16 in Binghamton, N. Y., to $2.08 in Chicago, Ill. In other shops, wage scales ranged from $1.01 an hour in Portland, Maine, to $1.86 in Seattle, Wash.

Linotype Operators

In the late 1880's, a new machine, which was to revolutionize the composing room and the printing industries generally, came into use. This machine, the now famous linotype, sets type very much more rapidly than is possible by hand (as does the "intertype," a similar machine invented some years later). Reading from copy clipped t the machine's copyboard, the linotype or intertyp operator selects the letters and other character to be printed by operating a keyboard which ha about 90 keys. After he completes each line, h works a lever, and the machine then casts the line of type automatically in solid strips known a slugs. Other duties performed by the operator i clude removing type from the machine, puttin new pigs (blocks) of type metal into the meltin pot, and making adjustments. In shops having considerable number of linotype machines, ho ever, a machinist is usually employed who mak all but the minor adjustments directly connect with machine operation.

As linotype and intertype machines have co into wider and wider use, the number of operat needed has increased, until they are now the seco largest group of composing-room workers. I 1940, about 60,000 of them were employed. T largest numbers of such workers are in newspa and job shops, but some are employed in book a periodical houses and in service shops doing m chine typesetting for printing firms. Some li type operators have their own service shops.



Courtesy of U. S. Government Printing Office, Washington, D. C.

Linotype operator at the keyboard of a linotype machine.

Like hand compositors and typesetters, these machine operators are skilled journeymen. The apprenticeship requirements for their occupation are usually the same as for hand compositors, except that in the last 6 months of training the linotypist apprentice specializes and receives training in machine work. Qualifications needed by apprentices are much the same for machine as for hand typesetting. However, there is less need for artistic ability and more for mechanical aptitude, to help the linotypist understand the mechanism of his machine and make adjustments.

Employment Prospects

The employment outlook for skilled linotype (and intertype) operators during the next few years is very good in the country as a whole, although there may be an oversupply of workers in a few local areas, as in the case of hand compositors. There will also be a great many training opportunities in the next couple of years, and fewer openings for newcomers thereafter. The long-range outlook is, however, more favorable than for hand compositors. Employment of linotype operators has so far tended to rise. This upward trend is expected to continue for an indefinite number of years, although eventually technological and other factors may lead to a stable or even a declining trend in employment.

Earnings

Linotype operators tend to have much the same rates of pay as hand compositors. In July 1946, the average union scale for linotypists in newspaper shops was $1.85 an hour; in others, $1.69. Wage rates in newspaper plants ranged from $1.15 in York, Pa., to $2.08 in Chicago. Of the other shops, those in Portland, Maine, had the lowest scale, $1.01; those in Detroit, the highest, $1.85.

Monotype Keyboard Operators

Photograph by U. S. Department of Labor.

Journeyman operating monotype keyboard.

Another step forward in typesetting was the invention of the monotype keyboard and monotype casting machines. With these machines, it is possible to cast individual letters and other type characters automatically (instead of solid lines, as in linotyping) and to assemble the type automatically in long shallow trays known as galleys. The monotype has a keyboard similar to that of a typewriter, but with some 200 keys. Unlike the linotype, which does the whole typesetting job, the monotype keyboard machine only perforates a narrow roll of paper for use later in the separate casting machine.

The workers who operate the keyboard and make the many different adjustments needed ar called monotype keyboard operators (sometime simply monotype operators). They are a rathe small occupational group; only about 6,000 wer employed in 1940. Most of them work for boo or periodical houses; some few, for job and servic shops.

In general, qualifications for employment ar the same as for linotype operators.

Employment Prospects

In the country as a whole, qualified journeyme should find it easy to get jobs in this occupati for the next 2 or 3 years. In addition, employe will, for a few years, need many more traine than usual. The actual number of training oppo tunities will not be large, however, because t occupation is so small.

Openings are likely to become fewer after t next few years, as in other composing-room occ pations. Employment will probably tend to r indefinitely, however.

Earnings

Wage rates for monotype keyboard operat are generally the same as those for linot operators.

Photograph by U. S. Department of Labor.

Monotype caster operator adjusting position of newly cast type as it comes out of the machine.

Monotype Caster Operators

Vorkers in this occupation operate the mono-
pe casting machines previously referred to,
ich cast and assemble type automatically,
ded by the perforations in the rolls of paper
pared by the monotype keyboard operators.
e caster operators not only adjust and tend the
hines but usually are required to know the
hanism in order to make repairs. In shops
ing several casting machines, the operator
supervise unskilled workers who tend the
hines.

p to the present time, only one caster operator
been employed to about every three keyboard
ators, taking the printing industries as a
le. The occupation is therefore very small, employing only about 2,000 workers in 1940. The types of plants using caster operators are of course the same as for keyboard operators—chiefly book and periodical houses and, to some extent, job and service shops.

Qualifications for Employment

Most newcomers to this occupation learn to operate the machine at a monotype school. Training is then rounded out on the job. This experience is especially needed for the most skilled and best paying jobs in the occupation, which require an understanding of the mechanism of the caster and ability to make adjustments and repairs. Persons entering the occupation should be physically strong and in good health.

This is another occupation in which employment opportunities for experienced workers should be good, especially during the next few years. Employment is expected to rise at an even faster rate than among keyboard operators. There will be many more openings for newcomers than in the past. There is room, however, for only a limited number of new workers in this small occupation, and competition for the openings is likely to be keen.

Earnings

Most monotype caster operators have about the same wage rates as linotypists (p. 14). Those without responsibility for adjustments or repairs earn less.

Proofreaders

To guard against errors in the final printed product, it is customary to make proofs of type set-ups and read these carefully against the original copy. In small shops, journeyman typesetters and advanced apprentices may do the proofreading, which is considered very responsible work. In most large plants, however, particularly in the newspaper, book, and periodical industries, there are special proofreaders. Altogether, about 5,000 such workers were employed in 1940, including a good many women.

The work is done in one of two ways. Either the proofreader puts the proof and the copy side by side and reads one against the other, a line at a time, by himself, or he has the material read to him by a copyholder while he follows the proof. Where there are errors, he notes the corrections needed, using standard proofreaders' marks.

Workers usually enter the occupation from another composing-room job or a front-office job with the same company. Skilled compositors and composing-machine operators who are no longer able to do typesetting at the speeds required may take positions as proofreaders. Those who do so are allowed to keep their journeyman status, at least in union shops.

Photograph by U. S. Department of Labor.

Proofreaders following copy as copyholders read to them.

Knowledge of grammar, spelling, and punctuation is very important to help the proofreader find and correct errors. The work requires good hearing and good eyesight.

Employment Prospects

Increased printing activity is expected to mean rising employment of proofreaders in the next few years and also in the long run. Though most of the jobs will be filled by workers already in the printing industries, there will be a few openings for veterans and others with experience related to proofreading. Persons completely new to the fiel will have little if any chance for jobs.

Earnings

In union shops, proofreaders generally have th same wage scales as hand compositors (p. 12). I nonunion shops, however, the wage rates for proo readers, particularly women, are likely to be lowe In January 1942, for example, straight-tin hourly earnings were typically 95 cents to $1. for men but only 50 to 80 cents for women, takin union and nonunion shops together. Since th time, there have been sizable wage increases in th as in other printing occupations.

Electrotypers and Stereotypers

From the composing room, type forms often go to the electrotyping or stereotyping department (or to an independent service shop doing such work for printing firms). Electrotyping and stereotyping are two different processes, which have the same purpose—making metal press plates from the type forms. One reason why it may be necessary to use such plates, instead of printing lirectly from the forms, is that a number of dupli- ate plates may be needed (any number can be urned out by either electrotyping or stereotyp- ng). When a large edition of a book or magazine s printed, several plates must be used one after he other, to prevent the printing surfaces from ecoming too worn to make clear impressions. By eans of duplicate plates, printers can also use veral presses on the same job at the same time d thus finish a big run quickly. This is especially portant in daily newspaper plants, which have rush many thousands of papers onto the streets th news that is no more than an hour or two l. Furthermore, the rotary presses used in many plants require curved plates (which can be de by either process), and type forms are always

n electrotyping, a wax mold of the type form sually made, though lead or some other ma- al may be used instead. To make a wax mold, electrotyper first lays the type form on the of a power molding press. He then places on of the press a metal sheet coated with wax applies the pressure, thus obtaining an im- sion of the type form in the wax. The next r steps are to give the mold a thin coating opper by pouring copper-sulphate solution it (sometimes nickel is used instead) and to nd it in a battery tank filled with the same ion. When the current is turned on, a shell pper is deposited on top of the copper coat- When stripped from the mold, backed with , carefully finished, and mounted, this shell es a plate ready for use in the pressroom.

stereotyping process is much simpler, quick- d less expensive than electrotyping, but it ot yield as fine a plate. Stereotypers make of papier mâché (a strong material com- of paper pulp), instead of wax or lead. work involves placing a damp papier mâché pad on top of the type form and running both through a rolling machine. After the paper mold has been dried, it is used in casting a composition-lead plate, which needs only trimming to be ready for the pressroom.

Journeymen electrotypers and stereotypers must know how to handle all the tasks involved in their respective processes, although in practice they are often assigned to only one phase of the work.

Neither occupation is a large one. In 1940, only about 7,500 or 8,000 journeymen were employed in both trades. Electrotypers work mainly in large book and periodical plants or shops (often owned and run by one or two journeymen) which service the book and periodical industries. Stereotypers work mainly in newspaper plants or shops servicing newspaper publishers. Some large commercial shops and other kinds of printing plants also use a few men in these occupations.

Qualifications for Employment

To qualify for either type of work, a 5- or 6-year apprenticeship is usually required. The training is quite different for each trade; rarely do journeymen change from one occupation to the other.

Young men who wish to become electrotyper or stereotyper apprentices need the same educa-

Electrotyper placing wax mold on top of type form which is on bed of power molding press.

Photograph by U. S. Department of Labor.

ing trades (p. 9). In addition, mechanical training and courses in chemistry and metallurgy are useful.

In work rooms where electrotyping or stereotyping is done, there are frequently fumes and dust and the temperature and humidity are often extremely high. Moreover, the work involves lifting of very heavy plates and type forms. People entering the occupations should be strong enough and in good enough health to work under these conditions.

Employment Prospects

Journeyman electrotypers and stereotypers, like most other groups of skilled printing craftsmen, will generally find it easy to get jobs in the immediate future and will have a good chance of holding their jobs indefinitely. Some men with all-round experience and managerial abilities will be able to go into business for themselves, with fair chances of success. There will also be more training opportunities than usual at least for a year or two. Openings for both journeymen and trainees will, at best, total no more than a few hundred a year, however—including vacancies due to turnover and also the new jobs which are expected to arise in the immediate future and over the long run.

Jobs and business opportunities for electrotypers and stereotypers are available in fewer localities than for most other groups of printing workers. They will seldom be found outside large industrial areas and will be mainly in or around New York, Chicago, Philadelphia, Detroit, and Cincinnati.

Earnings

Wage rates for electrotypers tended to be higher than those for any other occupation except photoengravers. The average union scale for electrotypers was $1.87 an hour in July 1946.

Photograph by U. S. Department of Labor.

Stereotyper holding mold which he has just removed from newly cast lead plate. He is about to pull the plate from the machine (an automatic tubular vacuum casting machine). Hot lead plate shows white in picture.

Stereotypers (in newspaper printing) had considerably lower pay, the average rate being $1.7 an hour.

The pay of electrotypers and stereotypers varie rather widely from one city to another. The lowest union rate for electrotypers in July 1946 wa $1.15 an hour in Nashville, Tenn.; the highe $2.10 in New York City, Chicago, and Newar Rates for stereotypers ranged from $1.15 an ho in Little Rock, Ark., to $2.00 in San Francisc Calif. Stereotyper rates also varied considerab from one branch of printing to another; the co paratively few men in periodical printing tend to have the highest pay.

Photoengravers and Rotogravure Photoengravers

Photoengravers enter into the printing process when copy to be reproduced by letterpress includes pictures or designs. As has already been mentioned, the photoengraving department supplies the composing room with any needed plates of illustrations and other material that cannot be set up in type. On these plates, the printing surfaces stand out in relief above the nonprinting spaces, as do the letters on the accompanying type.

Rotogravure photoengravers also make plates for use in reproducing pictures, but these are gravure plates with the image etched below the surface. The printing has to be done on special rotogravure presses, and often the entire process, from preparation of the plates through printing, is car- ied out in separate plants specializing in this kind of work.

Photoengravers

Photoengravers are skilled journeymen, able to andle all the operations involved in their process. ometimes, the entire job of producing a plate is one by one man. More often, however, especially large shops, the work is divided among a num- er of photoengravers, who may then be known by ich titles as photographer, printer, etcher, fin- her, router, blocker, or prover, according to the rticular phase of the work handled.

The photographer starts the process by photo- aphing the material to be reproduced, using the cessary screens or color filters, and develops the gative. Making a print from the negative on a etal plate coated with sensitized solution is the of the printer. Since the coating over the age areas of the plate is hardened by exposure light during the printing process or by further emical treatment, these areas are protected inst the acid into which the plate is put by etcher. The background areas are, however, ned away by this acid, leaving the image standout in relief. After that, there are still a few e operations to be carried out—including fin- ng (careful inspection and touching up with d tools), routing (cutting away metal from the printing parts of the plate to prevent them touching the inking roller during printing), blocking (mounting the engraving on a wooden block to make it the right height), and proving (printing a sample copy on a proof press).

Somewhat less than 10,000 men were employed as photoengravers in 1940, including both all-round men and specialists. The largest number work in service shops whose main business is making photoengravings for use by others; many journeymen have their own shops. Newspaper plants, book and periodical houses, and the United States Government Printing Office and Bureau of Engraving and Printing also employ considerable numbers of photoengravers.

Qualifications for Employment

A 6-year apprenticeship is generally required to become a journeyman. The training covers all phases of the process and includes a large amount (864 hours) of classroom instruction.

Since photoengravers' duties involve constant, close work with their eyes, good eyesight is essential in this occupation. Because of the work with acids and other chemicals which give off fumes, the occupation is not a good one for people with respiratory disabilities. Many employers require physical examinations for prospective photoengravers, testing both eyes and lungs. Among the types of school training which are helpful, in addition to those needed for all printing trades (p. 9), are courses in chemistry and metallurgy.

Employment Prospects

Employment opportunities for qualified journeymen are expected to be fairly good in this small occupation in the immediate future. Some men with all-round experience and business abilities should find favorable opportunities to open their own shops. There will not be many openings for apprentices during the next year or two, however—probably no more than a hundred or so in the entire country.

In the long run, employment is likely to level off, and openings for both journeymen and apprentices will probably be few.

Photograph by U. S. Department of Labor.

Photoengraver (etcher) using magnifying glass to inspect depth of "bite" in plate which he has just removed from acid bath.

Earnings

Photoengravers have, on the whole, higher wage rates than any other group of printing craftsmen studied, with the exception of rotogravure men. In July 1946, the average union scale for photoengravers in newspaper plants was $2.06 an hour; in other shops, $1.97. Although rates were highest in the New York City area (about $2.25 an hour), other metropolitan areas also had high pay scales. The lowest scale for union photoengravers in any of the cities where a survey was made was $1.35.

Rotogravure Photoengravers

Rotogravure work is a relatively new process, which was being used increasingly before the war. So far, however, it has never employed more than a few hundred journeymen in the entire countr

These men are a very highly skilled group. Li regular photoengravers, they are required to kn all phases of their process, although they usual specialize in one of them. The operations wh they handle are much like those involved in pho engraving, except that a positive (instead of negative) is used in making the plate and it the image (rather than the background) ar which are etched away.

A few large newspaper and commercial pla have departments which reproduce pictures this method. However, rotogravure men are ployed mainly in independent rotogravure pla Most of them work for half a dozen big fi which handle a large proportion of all rotogra work.

Photoengraver (router) cutting away metal from nonprinting areas of a plate. Photograph by U. S. Department of Labor.

Qualifications for Employment

t is possible to enter the occupation either by
-year apprenticeship in a rotogravure shop or
transferring from photoengraving. Photoen-
vers are usually required to complete a pro-
onary training period before being classified
skilled rotogravure men. The qualifications
led by apprentices are the same for rotogra-
e work as for photoengraving.

Employment Prospects

here will be little room for newcomers in this
pation during the next year or so. During the
the amount of rotogravure printing was much
ced, and a large proportion of the journeymen
apprentices either went into the armed services or transferred to photoengraving. The volume of rotogravure work is now rapidly returning to prewar levels, and there is frequent need for additional workers. However, these openings are being filled in most instances by former workers returning to the trade. Since the occupation is expected to go on expanding for an indefinite period, there should be some opportunities for newcomers after another year or two—but only a very few each year, because the total number of men employed is so small.

Earnings

As already indicated, rotogravure men are among the highest paid printing craftsmen. In general, their wage scales are above even the high rates for photoengravers doing letterpress work (p. 20).

Lithographic Occupations

Any kind of printing job that can be done by letterpress or gravure can be done also by lithography (or offset printing). Which method is used, however, depends on many practical considerations. Lithography has special advantages when the copy to be reproduced includes photographs, drawings, or paintings and particularly when these are in color. In present-day lithographic work, the plates are usually made by a photographic process, and the method is often referred to as photolithography. There are a few types of work—posters, for example—in which some of the plates are still made by hand.

The largest group of lithographic workers is made up of platemakers; other major occupational groups are cameramen, artists and letterers, pressmen, and press assistants. This section deals with the first three of these groups and with an occupation not yet mentioned, that of cutter. Information on lithographic pressmen is given in the section on pressroom occupations (p. 25).

Nature of the Work

Cameramen

The cameramen who photograph the copy to be printed are highly skilled workers. They do several different kinds of photography—in black and white or in color; of drawings or photographs: on glass plates or negative paper or film. The work includes not only taking the pictures and developing the negatives, but also related duties. Almost always, cameramen specialize in only one type of photography.

Artists and Letterers

After negatives have been made and developed they frequently have to be retouched, to lighten o intensify certain parts. This is done by hand, wit chemicals and dyes, and is one of the many highl skilled operations handled by craftsmen in the ar department. Artists may have to correct color

Artists preparing copy for reproduction by lithography.

Courtesy of U. S. Government Printing Office, Washington, D. C.

or other pictures on stone or metal plates or on special paper, on the comparatively rare occasions when hand methods are used in place of photolithography. Lettering is usually done by hand, lthough sometimes by machine.

To be journeymen, artists have to be adept either n one or more of the various retouching methods or in hand drawing with lithographic crayon. ike cameramen, they are customarily assigned to nly one phase of the work and may then be known, or example, as dot etchers (who do a highly pecialized type of retouching), retouchers, crayon rtists, or letterers, depending on their particular ob.

Platemakers

In photolithography, negatives and positives ade by cameramen and corrected by artists are ansferred onto press plates by workers in the atemaking or chemical department. The worker

coating in a vacuum frame or photocomposing machine; puts a photographic negative (or, sometimes a positive) on top of it; and makes an exposure under an arc lamp. The plate is then developed and chemically treated, so as to make the nonimage areas repellant to grease when damp but to leave the image areas receptive to it. The foregoing indicates only a few of the main steps in this highly complicated and technical process. Platemakers in small shops often perform all the different operations. Those in large shops, however, are likely to be more specialized; they may, for example, operate only a vacuum frame or a photocomposing machine.

Besides platemakers using these photomechanical methods, there are some who do hand transferring—although this process has been largely displaced by photomechanical platemaking. The hand-transfer platemaker places special transfer paper on a design and runs both through a transfer

Platemakers coating and developing lithographic plates.

Courtesy of U. S. Government Printing Office, Washington, D. C.

which now has on it the image to be reproduced, places it on the press plate, and presses the design into the grain of the plate. Finally, he treats the plate in various ways. He may also have other duties to perform.

Cutters

For persons who wish jobs in lithography but who are unable to qualify for work in the other occupations discussed, one of the most interesting possibilities is a position as paper trimmer or cutter. The work is similar in many ways to that done by cutters in other branches of printing and in some industries outside the printing group. These workers may use cutting machines not only to cut paper to the sizes needed for the press, but also to cut the large press sheets after printing, in order to separate the different items which were printed together. The cuts must be carefully planned and accurately carried out. Cutters are also responsible for adjusting the knives, clamps, and other devices on their cutting machines and for the upkeep of the machines.

Numbers Employed and Places of Employment

Since lithography is used to only a limited extent compared with letterpress printing, all the occupations that have been discussed are small. About 5,000 platemakers were employed in 1946. Pressmen totaled about 3,300 or 3,400, and their assistants around 4,000. Artists and letterers numbered approximately 3,000; cameramen, about 1,200, and cutters, roughly 1,000.

Most workers in these occupations are employed in plants specializing in lithography. However, a good many work in job shops or other letterpress plants which have lithographic departments, or for firms in other industries which do printing of their own by the lithographic process.

Qualifications for Employment

To become an all-round, skilled cameraman, artist, or platemaker generally requires a 4- or 5-year apprenticeship covering all phases of the given department's work. For less-skilled jobs

shorter periods of training are needed. Besides on-the-job training, many plants give supplementary training courses. Training programs are offered also in organized trade schools and other places.

The educational and physical qualifications needed for lithographic occupations are much the same as for printing occupations in general (p. 9). Men with physical handicaps of many types can qualify for jobs.

Employment Prospects

Qualified craftsmen should have little trouble getting jobs in lithographic occupations during the years immediately ahead. The labor shortages which developed during the war have been relieved only in part since VJ-day. Moreover, this is the fastest growing printing process. Employment opportunities will probably be very good als for men with training and experience in semiskilled lithographic occupations. In addition, employers will, for some time, need more traine than usual, but the actual number of openings fo newcomers will not be large in any occupation i any one year.

A few men will find favorable opportunities open their own shops. The chances are likely be best in localities which do not already have well-established lithographic business.

The long-run outlook is for continued rapid ris in employment in all major lithographic occup tions. Although by far the largest numbers f job openings—probably half of the total—will e in three cities (New York, Chicago, and San Fra cisco) during the next few years, opportunities w l become more and more widespread as time goes n.

Earnings

Skilled cameramen, artists, and platema rs were generally paid more than $1 an hour— quently much more—in the last years before he war. Cutters usually made between 80 cents nd $1 an hour. By the fall of 1946, wage rates increased on the average by at least 25 percen in these occupations. Since that time, wages ve risen still higher.

Pressroom Occupations

Type forms from composing rooms, press plates rom electrotyping and stereotyping departments, otogravure plates, and lithographic plates all go o a pressroom, when the time comes for the actual rinting to be done. In small shops, this depart- ent may consist of only one or two small presses a back room or a corner of the shop. In big ants, however, pressrooms are large, with many orkers and, frequently, huge presses. Often ese machines are so heavy and create so much bration that the department has to be located on e ground floor or in the basement.

Pressmen

Skilled pressmen, the key workers in the de- rtment, are the third largest group of printing craftsmen. In 1940, about 33,000 of them were employed. Only hand compositors and linotype operators were more numerous.

Pressmen's basic duties are to "make-ready" and then tend the presses while in operation. The object of the make-ready, which is one of the most delicate and difficult parts of the work, is to ensure printing impressions that are distinct and even and neither too dark nor too light. This is accomplished by such means as placing pieces of paper of exactly the right thicknesses underneath low areas of the press plate or type form to level it, and attaching pieces of tissue paper to the surface of the cylinder or flat platen which makes the impression. Pressmen also have to make many other adjustments—for example, those controlling

Pressman using paper to level plate. Press is a small flatbed cylinder press for letterpress printing.

Photograph by U. S. Department of Labor.

)

margins and the flow of ink to the inking roller. In some shops, they are responsible not only for tending the presses but for oiling and cleaning them and making at least minor repairs. In many cases they have assistants whose work they supervise.

Within this broad outline, pressmen's work varies greatly from one type of shop to another, because of the great differences in the kinds and sizes of presses used. Small commercial shops, many of which are owned and run by pressmen themselves in partnership with compositors, generally have small and relatively simple platen (or job) presses that are often fed paper by hand. At the other extreme are the big newspaper plants with their tremendous web-rotary presses. These giant presses are fed paper in big rolls (or webs). They print the paper on both sides by means of a series of cylinders; cut the pages apart, and assemble, and fold them; and finally count the finished newspaper sections, which emerge from the press ready for the mailing room. To do all this automatically requires many different mechanisms, all of which must have frequent attention while a run is being made. Presses of this kind are therefore operated by crews of journeymen and less-skilled workers, under the direction of a pressman-in-charge.

Another type of press on which men specialize is that used in offset printing. An offset press has three cylinders, the first carrying the curved plate; the second, a rubber blanket; and the third, the paper on which an impression is to be made. The plate does not print directly onto the paper but instead transfers the impression to the rubber blanket around the second cylinder which then offsets the image onto the paper. Another special feature is the dampening rollers which pass over the plate before each inking, to prevent the greasy ink from adhering to the nonprinting areas of the plate. Both these features create extra complications for the pressman. Experts emphasize also that, in printing by this method, "kiss" pressure only is needed (much less pressure than is involved in relief and gravure printing), and that delicate and skillful adjustments by the pressman are required to attain exactly the right pressure.

Pressmen may specialize also in operating direct lithographic presses, which make impressions on paper directly from lithographic plates instead of using the offset principle. There are, in addition, other types of presses including the rotogravure press, a rotary press with a "doctor" blade which scrapes the surplus ink off the surface of the plate.

Qualifications for Employment

To become a skilled pressman requires 3 to years of apprenticeship. Usually, men receiv training on only one type of press, and opinio differs as to how readily journeymen can becom skilled on other types of presses. The length the apprenticeship and the content of the trainin largely depend on the kind of press involved. F work on an offset press, for example, the appren ticeship period is almost always 5 years.

Apprentices are generally chosen from amon the press assistants and others already employ by the company. They must have completed least the eighth grade in school; some employe require high-school graduation. Since they w often have to blend their own inks, a knowledge f color is necessary. Courses in art are theref very helpful.

Physical strength and endurance are necess for work on some kinds of presses, where the pres man has to lift heavy type forms and press pl and be on his feet all day. Another quality nee is mechanical aptitude, to assist the worker in making adjustments and repairs to the presse

Employment Prospects

In this as in most other printing occupations, employers will need all qualified journeymen likely to be available during the next few years. In addition, there will be many apprenticeship opportunities, especially as new machinery becomes available. Proportionately speaking, the greatest increases in employment will be in lithographic work. Nevertheless, openings in this branch of the occupation will be few, because the total number of lithographic pressmen employed is small (about 3,300 or 3,400 in 1946). In the long run employment of pressmen will probably have an upward trend, as it had before the war.

Earnings

Wage rates for pressmen depend on the make and style of press operated, as well as the type of printing plant and other factors. Rates were highest in the newspaper industry, where pres

journeymen, $1.76 in July 1946. Outside news-
paper plants, the average union scale for cylinder
pressmen was $1.65 an hour; for platen pressmen,
;1.42. Of the pressmen for whom information
vas available, all but platen pressmen tended to
ave rates well above the average ($1.58) for all
rinting trades.

Press Assistants

The duties of press assistants range from merely
eding sheets of paper into hand-fed presses to
lping pressmen make ready and operate large
d complicated rotary presses. Workers whose
in responsibility is feeding are often referred
simply as feeders.

The nonjourneymen on web-rotary crews in
wspaper plants are commonly known as flyboys.
ey pick up the newspapers as they come out of
press and load them onto hand trucks; they
o wheel the trucks out of the pressroom and do
er work.

n 1940 the total number of press assistants em-
yed was roughly 8 or 9 thousand, not counting
oys in newspaper plants. The ratio of assist-
s to pressmen varies greatly from one establish-
t to another, depending on the size of the
t, the type of press used, and other factors.
y shops are too small to have any pressroom
ers.

ally to journeyman is possible for many though not all press assistants. Those who aspire to such promotions need the same general qualifications as are needed by apprentice pressmen (p. 26).

Employment Prospects

Several hundred job openings for press assistants may be expected each year for the next few years. After that, openings will probably become much fewer. Before the war, the printing industries tended not to hire as many press assistants as they lost owing to turn-over. It is likely that this tendency will appear again after the current need for labor has been met and that employment in the occupation will resume its long-range downward trend. However, lay-offs will probably be made only in exceptional circumstances.

Earnings

In July 1946, press assistants in union shops outside the newspaper industry had an average wage rate of $1.32 an hour. Those who were merely press feeders had somewhat lower pay than the ones whose main job was to assist journeymen in the make-ready and in operating the presses. Helpers in newspaper pressrooms made less than press assistants in other printing shops, although the reverse was true for skilled pressmen.

Bindery Occupations

ny products are finished when they leave the
room. This is true of a wide variety of items
iced by job shops—business forms, printed
nery, labels, advertising flyers, and so forth.
papers, except the few that are bound for
ies, never see a bindery department. Never-
s, binderies play a part in the manufacture
ny products besides books. Whenever a
ine or pamphlet or even a small calendar
ed or stapled together, this is considered a
y operation.

Bookbinders

ing a book out of the big, flat sheets of paper
me into the bindery from the pressroom is
he most complicated type of bindery work.
st step is to fold the printed sheets, each of
which contains many pages, so that these pages will be in the right order. When so folded into sections of 16 or 32 pages, the sheets are known as signatures. The next steps are to insert any illustrations that have been printed separately, to assemble the signatures in proper order, and to sew them together. The resulting book bodies are shaped in various ways, usually with power presses and trimming machines, and fabric strips are glued to the backs to reinforce them. Sometimes, the edges of the pages are gilded or colored. Covers are glued or pasted onto the book bodies, after which the books undergo a variety of finishing operations and, frequently, are wrapped in paper jackets.

Skilled bookbinders seldom handle all these different tasks, although many journeymen have had training in all of them. Especially in large shops, a few operations, most often to the operation of complicated machines.

The majority of journeymen are employed in shops whose main business is bookbinding. However, a good many work in the bindery rooms of large book, periodical, and commercial printing plants. Some are employed in libraries, where the work is done mainly by hand and also differs in other respects from that performed elsewhere. Rough estimates suggest that, altogether, about 15 or 20 thousand men had journeyman jobs in 1940, making this the fourth largest group of printing craftsmen.

Qualifications for Employment

Completion of a 4-year apprenticeship is usually required of men seeking to qualify as skilled bookbinders. The apprenticeship programs may vary considerably between the different types of shops. Where large quantities of books are bound on a mass-production basis, emphasis is on the most modern machine methods. Where fine hand binding is done, the training is mainly in hand methods, including artistic designing and decorations of leather covers.

Bookbinder putting gold lettering on back of book with hand tool.

Photograph by U. S. Department of Labor.

Both journeyman and apprentice openings will be more numerous during the next few years than they were for many years before the war. The occupation was greatly overcrowded in the last prewar years; thousands of skilled workers were unemployed or had been forced to take jobs paying less than a journeyman's wage. During the war, a labor shortage developed in this occupation, as in printing crafts generally, and there are still many openings. The shortage is unlikely to last more than a few years longer, however. It is expected that eventually the number of opportunities will be small and that employment in the occupation will resume its long-run downward trend.

Earnings

Union rates for journeyman bookbinders averaged $1.50 an hour in July 1946. For over two-thirds of these skilled workers, wage scales were between $1.30 and $1.60 per hour. In general, pay scales in the occupation were below the average ($1.58) for all printing trades.

Bindery Workers

In many binderies, especially large ones, a great part of the work is done by employees trained in only one operation or in a small group of related tasks. These semiskilled workers are mostly women, though a few are men. The women handle a variety of hand or light-machine operations—such as hand folding, pasting-in of inserts, assembling signatures by hand, machine sewing, and gluing fabric reinforcement on signatures, and feeding machines. The men are usually assigned to more intricate machine jobs; they may operate assembling, trimming, stamping, and many other types of machines.

The bindery workers are by far the largest group of semiskilled workers in the printing and allied industries. Roughly 70 or 80 thousand of them were employed in 1940. Large numbers are used both in independent binderies and in the bindery departments of big printing plants. For inexperienced men and women entering the occupation, a training period, which may be as long as 1 or 2 years, is frequently required. In union shops, there are always formal training programs.

Photograph by U. S. Department of Labor.

Bindery workers "casing-in" small booklets (putting covers on pages). Girl at far right is running cover through machine which puts glue on inside. Girl in the center is inserting pages in cover. Man is straightening pages and folding booklets.

Employment Prospects

or several years, experienced workers will ably have little difficulty in getting jobs in occupation. There will also be hundreds of ings for inexperienced workers each year. r the next few years, opportunities are likely come fewer and there may not be enough jobs ll persons seeking work. But the long-run l of employment is upward, as in most printccupations. Workers who now have jobs or enter the field during the current expansion ployment will have a good chance of keeping positions indefinitely.

Earnings

Women bindery workers have the lowest wage rates of any group of production workers in the printing and allied industries. In July 1946, the average union scale for these women was 81 cents an hour, with 9 out of 10 having rates between 70 cents and $1.00. These union scales were probably representative of all wage rates for women in the occupation although, unlike printing workers, many bindery employees, especially women, are not covered by union agreements.

Men doing semiskilled machine work were generally paid somewhat more than the usual top rate for women. The few doing hand operations had rates similar to those for women workers.

APPENDIXES

1. Number of Establishments, Value of Products, and Number of Persons Employed in Printing, Publishing, and Allied Industries, 1939 [1]

Industry [2]	Number of establishments	Value of products (millions of dollars)	Number employed

---

[1] Census of Manufactures, vol. II, pt. I, 1939; and Census of Business, vol. III, Service Establishments, 1939.

[2] The industry in which an establishment was classified by the Bureau of the Census was determined by its chief product or products (measu dollar value of output during 1939), except in the case of newspaper printing. Plants which had done any work of this type during 1939 were classed newspaper industry, even if they had also done commercial or other work having a greater value. See the U. S. Department of Commerce, Bureau the Census, *Industry Classifications for the Census of Manufactures, 1939*, pp. 1 and 46–48.

[3] This industry is made up of establishments primarily engaged in preparing lithograph plates and in printing from such plates. The greater the work is done to individual order, but in some cases lithographed calendars, commercial forms, maps, illustrated cards, posters, and other items are for sale. Lithographing of books and pamphlets for publishers is classified in the book printing industry. A great many plants, classified in other pr industries or outside the printing group, do some lithographic work; the Joint Lithographic Advisory Council estimates that at least 2,000 separate lishments had lithographic equipment in 1939 and that, by 1946, the number had increased to about 2,600.

[4] Most establishments in this industry are rotogravure plants, which make plates of pictures by a photo-mechanical process and also print from these Some few do other types of gravure printing.

[5] These shops service the printing industries with plates engraved by hand or machine and sometimes also print from the plates they make.

VI. Occupational Outlook Publications of the Bureau of Labor Statistics

Studies of employment trends and opportunities in the various occupations and professions are made by the Occupational Outlook Service of the Bureau of Labor Statistics.

Reports are prepared for use in the vocational guidance of veterans, young people in schools, and others considering the choice of an occupation. Schools concerned with vocational training and employers and trade-unions interested in on-the-job training have also found the reports helpful in planning programs in line with prospective employment opportunities.

Occupational outlook reports are issued as bulletins of the Bureau of Labor Statistics: sometimes they are also published in the Monthly Labor Review (subscription per year, $3.50; single copy 30 cents). Both the Monthly Labor Review and the bulletins may be purchased from the Superintendent of Documents, Washington 25, D. C.

Two types of reports are issued:

Occupational outlook bulletins describe the long-run outlook for employment in each occupation and give information on earnings, working conditions, and the training required.

Special bulletins are issued from time to time on such subjects as the general employment outlook, trends in the various States, and occupational mobility.

Occupational Outlook Bulletins

Employment Opportunities for Diesel-Engine Mechanics

Bulletin No. 813 (1945), price 5 cents. (Monthly Labor Review, February 1945).

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., May 19, 1947.

The Secretary of Labor:

I have the honor to transmit herewith the annual report on union wage rates of local transit operating employees, as of July 1, 1946.

This report was prepared in the Bureau's Wage Analysis Branch by Herbert M. Abowitz, under the direction of Donald H. Gerrish.

Ewan Clague,
Commissioner

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 903 of the
United States Bureau of Labor Statistics

Union Wages and Hours of Local Transit Operating Employees, July 1, 1946

Summary

Basic wage rates of union streetcar and bus operators averaged $1.10 an hour for 72 cities on July 1, 1946, an increase of 17.2 percent over July 1, 1945. The increase reflects the inclusion of many wartime bonus arrangements as part of the basic rate structure along with the postwar negotiated increases. Ninety-seven percent of the union members received rate increases. Two-fifths of those benefiting advanced by 15 to 20 percent. Shortening of time intervals between automatic wage increases benefited 6 percent of the workers. The highest rates were reported in Detroit where operators of one-man cars had a rate of $1.32 an hour after 1 year of service, with 10 cents additional for owl runs.

Overtime payments after a specified number of hours of work and the 40-hour straight-time week are becoming increasingly prevalent. All of the workers studied were covered by agreements providing paid vacations, and 57 percent received 2 weeks' vacation after 1 year of service.

Scope of Study

This survey, first conducted in 1921, is part of the Bureau of Labor Statistics program of making Nation-wide annual studies of union vage scales and related matters in various trades.[1] Union scales erein reported for the various classifications covering organized treetcar, bus, and subway operating employees working on local city ransit services were those in effect on July 1, 1946. A union scale nay be defined as the minimum rates or maximum number of hours of vork at straight-time agreed upon by the employer and the union for a articular trade in a given locality. Scales negotiated subsequent to the survey date were reexamined wherever possible to insure inclusion of wage changes retroactive to July 1, 1946.

---

[1] The data upon which this report is based were collected by field representatives of the Bureau from icials of the local trade unions in 75 principal cities of the United States. Wherever adequate membership eak-down at the various rate levels was unobtainable at the union office, the data were secured from mpany officials.

Operators of municipally owned intracity transit systems were included in the survey if unions acted as bargaining agents for the employees. Trackmen and maintenance workers were excluded. Of the 75 cities surveyed, 72 reported effective union agreements covering 102,164 local transit operating employees.

Trend of Hourly Wage Rates [2]

The index of hourly wage rates for union streetcar and bus operators stood at 143.1 on July 1, 1946, an increase of 17.2 percent from the preceding study (July 1, 1945). During war years many agreements in this industry provided for payment of bonuses, ranging from 2 to 7 cents an hour in different cities in addition to the basic hourly rate. During the past year most of the collective bargaining agreements in the industry made the average bonus payments a part of the basic wage structure, and provided additional increases over and above previous rates plus bonus. The bonuses were not included in previous studies as they were not a part of the rate structure although they were actually being paid. The 17.2-percent increase mentioned above, therefore, actually includes, in addition to negotiated rate increases, the bonus payments effective in war years but not recorded in the Bureau's earlier studies. Wage rates in this industry hav shown gradual improvement since 1934. The most pronounce changes occurred in 1942 when a 7.3-percent increase from the preceding year was recorded.

TABLE 1.—*Indexes of hourly wage rates of local transit operating employees, 1929–46*

[1939=100]

Year	Index	Year	Index	Year	Index
1929	91.6	1935	91.4	1941	104
1930	92.5	1936	92.1	1942	112

[2] In computing the index series (1939=100), the annual percentage change from year to year is derived fr aggregates of union quotations for identical classifications in 2 successive years. The membership weig in both of the aggregates used for each year to year comparison are those reported for the second year. obtain the index for the current year, the total of the current aggregates is divided by the previous ye aggregates and the ratio thus obtained is multiplied by the previous year's index number. The inde are computed on this basis in order to minimize the effect of changes in union membership which mi obscure the real changes in wages. The index series, rather than the actual averages of rates in this and p vious reports, should be used to determine the trend of hourly wage rates. Changes in coverage and s in union membership distort a direct comparison of average rates in two periods.

Increases in average basic scales between July 1, 1945, and July 1, 1946, and incorporation of bonuses in these scales were mainly responsible for the upward movement in rates. Nevertheless, approximately 6 percent of the total membership concentrated in seven widely scattered cities benefited by rate adjustments brought about by the reduction of time intervals between automatic wage increases under contracts providing for graduated scales.

Hourly Wage Rates, July 1, 1946

Organized streetcar and bus operators in 72 cities averaged $1.10 an hour on July 1, 1946. Fifty-five percent of the workers received between $1 and $1.15, and of these a majority had hourly rates ranging from $1.10 to $1.15. Less than 7 percent of the workers had hourly rates below the July 1, 1945, national average of 94.4 cents. Rates of at least $1 an hour were reported by 8 of every 10 members n contrast to 2 out of 10 revealed in the preceding survey. Twenty-hree percent of the workers reported scales of at least $1.20, but of hese a majority did not receive as much as $1.25.

As previously indicated, the comparisons between 1945 and 1946 re necessarily limited to the basic rate structures in effect on the urvey dates, and do not include additions to basic scales, such as he various wartime bonus arrangements existing in 30 covered cities st year. These increments, varying from pay period to pay period, rved to increase operators' hourly earnings. Bonus plans approved y the War Labor Board could not exceed 7 cents per hour. However, ans in operation before the War Labor Board's order were not fected. In one city (Binghamton, N. Y.), the bonus plan provided n additional 17 cents to the operators' hourly rate. This bonus, plus additional 6 cents per hour, was incorporated into the basic rate ucture by the time of the current survey.

Streetcar and bus operators were usually paid on a graduated scale sed on the employee's length of service with the company. The riod between rate changes varied considerably among different ies ranging from 1½ months for some classifications in Philadelphia as long as 1 year in several cities. Most agreements stipulated entrance, an intermediate, and a maximum rate.[3] Most frequently, latter applied after completion of 1 or 2 years' service, though me agreements had such provisions ranging from 6 months (Jack-, Miss.) to 4 years (New York City) and as many as seven progres-n steps from entrance rate through the maximum rate. There

---

his so-called "maximum rate" is actually the minimum union scale after a specified period of employ-with the company, and is not a maximum rate in the sense that the company may not pay more.

was great variance in the differences between entrance and maximum rates among cities and among companies operating within a city. Although the differentials were generally 5, 8, or 10 cents, differences of from 2 to as much as 27 cents an hour were reported.

Rates for operators and conductors on two-man cars, reported by 20 cities, were lower than those effective for operators of one-man vehicles in those cities. Although the maximum rate was generally about 10 cents an hour higher for the one-man car and bus operators, differences of 5 and 7 cents were also frequent.

Entrance rates for one-man vehicle operators ranged from 68 cents an hour in Nashville, Tenn., to $1.24 in Chicago, while for operators and conductors on two-man cars entrance rates ranged from 79 cents in Omaha, Nebr., to $1.12 in Detroit, Mich. In those cities where two-man vehicles are utilized no wage differential exists between the rate applying to conductors and motormen. In many instances the conductor may be a low seniority man and consequently fall within the lower bracket of the same scale progression. Generally the two classifications are interchangeable.

Maximum rates for one-man vehicle operators varied from 80 cents in Madison, Wis., Wichita, Kans., and York, Pa., to $1.32 in Detroit, Mich., where an additional 10 cents an hour was paid for work on owl runs. For two-man vehicle operators, the maximum hourly rate ranged from 86 cents in Omaha, Nebr., to $1.22 in Detroit (10 cents additional for owl runs).

TABLE 2.—*Percentage distribution of union operating employees in the local transi industry by hourly wage rates, July 1, 1946*

Hourly wage rates	Percent of union members by occupation			
	All workers	Operators of 1-man cars and busses	Motormen and conductors of 2-man surface cars	Elevated and subwa operators
Under 80 cents	0.6	1.1	(1)	----------
80 and under 85 cents	.9	1.4	0.2	----------
85 and under 90 cents	1.7	1.9	1.9	----------

$1.35 and over	2.2	.1	----------	

[1] Less than 0.05 of 1 percent.

Changes in Wage Rates Between 1945 and 1946

Almost all (97 percent) of the organized local transit workers received increases in basic rates after July 1, 1945. Two-fifths of the members reported increases of 15 to 20 percent, and almost a third benefited by gains of 20 to 30 percent. Although the July 1, 1945, study revealed but 2 percent of the members as having secured improvement in basic rates to the extent of 10 percent or more, considerably over 90 percent of the members had registered gains at or above this level by July 1, 1946.

Among about 55 percent of the one-man car operators, increases for half of them ranged from 10 to 15 percent and for the others from 15 to 20 percent. Most of the remaining operators in this category benefited by rates ranging from 20 to 30 percent higher than n the previous year. Nearly 6 of every 10 motormen and conductors n two-man vehicles reported gains of 15 to 20 percent, while threeuarters of those engaged in subway and elevated operations had aises of 15 to 25 percent. All of the remaining members in the atter group reported basic wage gains of at least 25 percent. It ust be remembered that these increases include in many cases the ddition of previously effective bonus payments to the basic rate ructure.

ABLE 3.—*Extent of changes in wage rates for local transit operating employees and percent of members affected by increases between July 1, 1945, and July 1, 1946*

Trade	Percent of members having—		Percent of members having increase of—							
	No change	Increase	Less than 5 percent	5 and under 10 percent	10 and under 15 percent	15 and under 20 percent	20 and under 25 percent	25 and under 30 percent	30 and under 35 percent	35 percent and over
local transit operating employees	3.1	96.9	0.9	2.8	23.1	39.6	16.6	12.6	1.3	(1)
rators of 1-man cars and busses	4.3	95.7	1.7	4.2	27.0	28.4	19.9	13.8	.7	(1)

ated and subway lines	------	100.0	------	------	------	40.9	34.3	24.2	.4	.2

ess than 0.05 of 1 percent.

Post Survey Rate Changes

ate increases in the local transit industry have become effective e July 1, 1946, in at least 12 cities, according to limited available rmation. Basic rate advances of at least 20 cents an hour were rted for bus operators in Chicago and New York. Members in hita effected a reduction in the time interval between rate progressions and benefited by 20 cents an hour if employed 18 months. Increases of 11, 12, and 13 cents, respectively, were reported for Staten Island bus operators, Columbus streetcar operators, and Salt Lake City bus operators. Among the cities for whom higher scales were reported for operators of one-man vehicles were Scranton (8 cents) and Rock Island and Spokane (5 cents). Smaller increases were reported in several other cities.

Weekly Hours and Overtime Rates [4]

The payment of overtime rates after a specified number of hours, regardless of the length of the run, is becoming increasingly prevalent. Previous Bureau of Labor Statistics reports revealed that one-third of the union members tabulated in 1944 worked under agreements providing for a limit on straight-time hours. The following year this proportion increased to three-quarters, and by July 1, 1946, almost 9 of every 10 union workers were covered by such hour limitations.

A run may be defined as a definite number of trips over a given route. Many runs are "swing runs," operated during the morning and afternoon rush hours, with a layoff of 4 or 5 hours in the middle of each day. Straight-time hours on swing runs are usually limited to specific periods spread over a wide time interval, with overtime pay at time-and-a-half required after a span of 12 or 13 hours a day Unions have for many years steadfastly worked to keep swing runs a a minimum, and this has been accomplished by contract stipulation requiring a large percentage of straight runs guaranteeing 40 or 4 hours' pay per week. Because an operator's take-home pay is dependent on the run, most union agreements provide for periodic selection o runs, usually every 3 or 6 months, on a seniority basis. Swing run and trippers are generally operated by low-seniority or "extra" mer

TABLE 4.—*Distribution of union local transit operating employees by weekly hours, July 1, 1946*

Occupation	Percentage of workers with straight-time weekly hours of—								
	40	Over 40 and under 44	44	45	48	Over 48 and under 51	51	Over 51	Lim ec only len, of r
All occupations	31.6	4.0	22.0	0.2	27.0	0.3	2.3	1.1	5

Elevated and subway lines	18.2	6.3	2.6	------	72.4	------	------	------	5

---

[4] Weekly hours considered here refer to the maximum number of hours a week permitted by union a ments before overtime rates become effective. The actual number of hours worked in any 1 week ma greater or less than the weekly hours discussed.

Although the Fair Labor Standards Act specifically exempted the street-railway industry from its penalty overtime provisions, because of the nature of local transit operations, overtime pay after 40 hours is receiving increasing acceptance. Whereas in 1944 but few members received overtime after 40 hours, the current study revealed over 30 percent of the membership covered by such contract provisions.

Straight-time hour limitations varied from 40 to 57 hours a week. About three-fifths of the members had a straight-time workweek of 4 hours or less and most of the remaining members with straight-ime hour limitations received overtime after 48 hours a week. During the study interval approximately 1 of every 10 members received reduction in the straight-time workweek. Should opportunity for vertime work exist these workers would be entitled to premium payent after the performance of fewer hours than formerly. Though w members working on two-man cars received hour reductions, over percent of the subway and elevated workers and about 12 percent the operators of one-man vehicles were so affected.

Virtually all of the workers engaged in local transit operations were vered by contracts providing for the payment of time and a half for rk performed either beyond the specified straight-time hours or on e completion of a definite run.

Vacations

ll the agreements in the 72 cities included in the survey provided paid vacations. Well over a majority of the members received a eeks' vacation after 1 year and almost a third received at least eek's vacation after 1 year. About one-eleventh of the members e covered by contracts providing other than standard vacation ses, such as 1 week after 1,280 hours' service and 2 weeks after 0 hours' service in Los Angeles, or 1 week's vacation for service ing from 160 to 192 working days and 2 weeks after 192 working in Worcester.

l the agreements containing other than customary vacation es provided for at least 1 week of vacation after 1 year and several ed additional days for a specified number of subsequent years vice.

Rates Paid in Each City

e union rates per hour in effect on July 1, 1946, and July 1, 1945, y, are shown in table 5.

State legislation 33
Decisions affecting cooperatives 34
Taxation of cooperatives 35

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., June 24, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on developments in the consumers' cooperative movement in 1946, prepared by Florence E. Parker of the Bureau's Labor Economics Staff.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Bulletin No. 904 of the
United States Bureau of Labor Statistics
[Reprinted from the MONTHLY LABOR REVIEW, March 1947, with additional data]

Developments in the Consumers' Cooperative Movement in 1946

Summary

TO COOPERATORS in the United States, the outstanding event of 1946 was the biennial Cooperative Congress, which made far-reaching changes in the structure of the organized cooperative movement in this country. The year was also notable for the substantial progress in the fields of cooperative housing and medical care; for the unusually large number of new branches opened or new departments added by established associations; and for the organization of national federations of cooperative housing associations, of cooperative medical-care associations, and of students' cooperatives, as well as of an international association to carry on trade in petroleum products among the cooperative movements of the various countries of the world.

There was continuance and expansion of previous efforts toward closer relationships with other groups, such as labor, churches, and farmers. Particularly successful have been the moves in the direction of labor, which are now paying dividends in the active support of cooperatives by unions and their members in many places.

Developments Among the Local Associations

As usual, many new distributive cooperatives were started during the year, and an unusually large number of associations opened new branches or added new departments. Electrical-appliance departments were among the most popular. According to report, some 2,300 local associations were dealing in electrical appliances by early 1947, but only 23 percent were carrying a full line. Other new departures included departments for building supplies, lumber yards, coal yards, a carpenter shop, general stores, gasoline stations, cold-storage lockers, dry-cleaning service, watch-repair service, a dry goods store, and a hardware store. One local association bought a sawmill, another an ice-cream plant, and a third a small petroleum refinery for heavy fuels. One association became an agency for the sale of small airplanes. In Connecticut a cooperative store association opened what was said to be the first cooperative gasoline station in that State.

Urban associations.—The year 1946 saw some advance in the spread of cooperation in urban areas. In Chicago, six existing associations had by August 1946 voted to become branches of the city-wide Chicago Consumers' Cooperative, formed in 1945. Each thereby became a "district assembly" of the association. Two others were reported as in process of formation. The first supermarket of the new association was opened in November 1946, and early in January 1947 the leasing of a site for a second was announced. The association's membership in September was stated to have passed 1,800.

Other cities were reported to be interested in the Chicago procedures, one of which is a $5 nonreturnable membership fee, used to defray the expense of a paid staff of organizers. "Another is the city-wide enlistment of members, with the gradual development of natural centers for intensive organizational work. The latter feature permits people who are sufficiently interested in co-ops to invest and participate before there is immediate prospect of a store in their neighborhood and create a common pool of capital for use throughout the city." [1]

In the Twin Cities, membership meetings approved a proposed merger of Cooperative Services (Minneapolis) and Co-ops, Inc. (St. Paul), under the name Twin Cities Cooperative Services. The Minneapolis group operates several automobile service stations and a feed, coal, and lumber yard; a food store was sold to the St. Paul association early in 1946. The latter was already operating five grocery stores and had just purchased a bakery to supply its stores. In Cheyenne, Wyo., the gas cooperative opened a supermarket in the spring of 1946. The two Berkeley, Calif., cooperatives (one operating a grocery store and the other a gasoline station and hardware and appliance store) merged to form the Berkeley Cooperative Center, with a combined membership of about 1,400.

In New York City, Consumers Cooperative Services, operating seven cafeterias and four grocery stores, reported the largest volume of business in its 26-year history in 1945–46 ($1,373,424) and an increase in membership from 5,536 to 7,130. Its plans call for an eventual chain of 20 stores within a 10-mile radius of its warehouse.

Greenbelt Consumers Services, in Greenbelt, Md. (within the metropolitan area of Washington, D. C., where many of its members are employed), had a business of $1,162,851 in 1945 and an increase to $1,428,586 in 1946. Membership also rose from 1,820 to nearly 2,000 in the first 6 months of 1946. The association is raising money for a new cooperative shopping center, to house a food market, restaurant, soda fountain, bakery, bowling alley, game room, and nursery. The association already operates all the other businesses in town (theater, barber shop, beauty parlor, and drug store). It also operates a bus service throughout the town. In the period 1940–45 the sum of $79,294 was returned to the patrons in savings.

---

[1] Co-op News (Chicago), November 20, 1946.

The need for intensified effort in organizing urban areas for cooperation was emphasized in a sectional meeting of the Cooperative Congress. Most of the speakers advocated organizing drives, financed either by nonreturnable membership fees or from the resources of an established local association or regional. Stress was laid upon the necessity of adequate capitalization before opening a new store or association, thus enabling the enterprise to operate efficiently and with a considerable volume, as well as to buy to advantage, thereby permitting it to be competitive with the chains. All the speakers favored a city-wide cooperative chain for large urban centers, and one speaker even favored centralized management of local associations by the regional wholesale, on the ground that it would coordinate cooperative efforts within the region, enable local needs to be reflected easily and quickly at the regional level, and provide better opportunities for employee advancement.

SPECIAL TYPES OF COOPERATIVES

Housing Associations

Progress of local associations.—Reports received by the Bureau of abor Statistics show that housing cooperatives are being formed all ver the country. Especially active are veterans for whom the housing ituation is very difficult but who have had priority above others in he building field and have the advantage of Government loans and uaranties. In some places veteran groups are undertaking the development of outlying tracts, including the installation of utilities, treets, etc.; in others, the association contemplates taking over xisting buildings for remodeling. One group is sponsoring a homeead development in Alaska. In the District of Columbia a veterans' ooperative was the successful bidder for Naylor Gardens—a 475-unit evelopment built by the Government during the war.

Types of dwellings planned range all the way from apartments, rough single-family dwellings on city lots, to subsistence homesteads ith land ranging up to several acres. In one case a students' coopative composed of veterans is erecting prefabricated houses on land ned by the university.

Numerous housing developments on the cooperative plan are being onsored by labor groups. In Washington, D. C., printing-trades rkers are planning an apartment-house project. In South Bend, Ind., members of a local of the UAW-CIO took the initiative in a housing cooperative to build single-family units. Employees of the Omaha district of the Corps of Engineers are reported to have initiated a contemplated suburban community of 600 homes; so detailed were their plans that they even included space for a helicopter landing field. Racine, Wis., is the scene of a housing project in which members of AFL and CIO unions, as well as the local consumers' cooperative, are participating.

In most cases a single project is planned, with membership limited to the prospective residents in the project. However, an identical type of open-membership technique has been adopted by two housing associations, one in New Haven, Conn., and the other in Washington, D. C., entirely independently of each other. In both cases a general open-membership cooperative acts as sponsoring and initiating agency for specific housing projects. Individuals desiring to reside in developments sponsored by the parent association must first join the latter. Ownership and control of the project eventually are turned over to a second association, composed entirely of residents of the project. Such an arrangement affords membership to many persons who do not themselves need living accommodations but are desirous of helping to further the cooperative housing plan, while at the same time it insures final control by the tenant-members of the conditions under which they live.

Numerous mutual housing associations are reported, formed to take over completed developments. In all cases that have thus far come to the attention of the Bureau, these intend to operate on the Rochdale principle of retention of title by the association, with the member receiving a lease to the dwelling he occupies. Of the permanent housing projects built under the defense housing program by the Federal Government, with funds supplied under the Lanham Act, eight were earmarked for "mutual ownership" after the war. These included three in New Jersey, one in Pennsylvania, one in Ohio, one in Indiana, and two in Texas.

Under the plan worked out, if the residents of the project desire to purchase the dwellings, they are required to form a nonprofit mutual home ownership corporation. The corporation is then given a 2-year lease, with option to buy at the end of that time (if it has demonstrated its ability to operate the property efficiently). At the end of December 1946, two corporations—one in South Bend, Ind., and the other in Dayton, Ohio—had served their 2-year probationary period and exercised their option. Appraisal of the property had been made and negotiations for purchase were in progress. The other six projects were being run by ownership corporations, but as their 2-year leases had not yet expired, no further step could yet be taken.

Federally built projects financed by other funds have also been put up for sale by the Defense Homes Corporation of the Federal Housing Agency. The Naylor Gardens project, already mentioned, was one of these. In August 1946 it was reported that a mutual housing association, formed for the purpose of bidding in the village of Greenbelt, Md., had obtained 200 members toward the 472 (25 percent of the total 1,887 dwellings) required in order to bid; by the end of the year more than half of the residents had indicated their desire for ownership. In Detroit it was reported that a move was on foot to form a mutual housing association to purchase Norwayne Homes there, with 50 percent of the tenants in favor of purchase.

In the Twin Cities of St. Paul and Minneapolis, an unusual housing development is under way. A complete village of 1,200 acres on the shore of a lake has been planned and is being built through the efforts of three cooperators, of whom one owned part of the necessary land, one was an architect, and the third was a contractor. In this project the resident-members come into a going concern, buying their lots and subscribing for shares. Each house will be financed individually, by the member. The village is to be developed section by section, as the lots are taken. The three developers each have one vote and hold all of the preferred stock. They will retain control until the project is under way, then surrender their votes "one at a time—to each group of 500 home owners as the village grows." In other words, not until 1,500 residents have moved in will the members have complete control of the project. Speculation is to be prevented by association control over the sale price, which is to be arrived at by an appraisal board of three (one representing the owners and one the association, and the third a neutral outsider).

The one cooperative project, as far as this Bureau's knowledge goes, to be undertaken thus far under an urban redevelopment law is the East River Cooperative Apartments in lower Manhattan, N. Y. This project is sponsored by a group of citizens, including the leader of the successful Amalgamated apartments in the same city. It will provide 796 apartments in 12-story buildings that will occupy only 25 percent of the land area of 4 city blocks. As the purpose of the act under which the project is being carried on is to promote slum clearance, the project will have the advantage of land obtained at condemnation rates and a 25-year tax exemption on the buildings. By mid-November 70 percent of the apartments had been applied for. The maximum cost of the project has been set at $7,000,000 and rentals may not exceed $15 per room.

Cooperative principles.—Only a few of the housing associations, except those in which dwellings are of the multiple-unit type, seem to be adopting all-the-way cooperative procedure. In several cases the planned function of the cooperative will be merely that of acquiring the site and contracting for the construction of the dwellings. Title will be given to individual members as they pay for their lots, and individual financing is to be arranged for the houses. In other cases the cooperative will also oversee the construction; it will not retain title to the completed units, but will relinquish them to individual purchasers. The data at hand do not in most cases reveal what, if any, restrictions are to be imposed in order to prevent speculation by the owners.

Where an entirely new subdivision or community is planned, in a number of cases it is intended that the housing association shall retain ownership of certain designated areas to be used for shopping facilities, recreation, or other community activities. In some cases, trading facilities are to be run by a cooperative organized for the purpose; in others, they are to be leased to private dealers.

In general, it appears that the extent of cooperative practice contemplated is in direct relationship to the degree of previous experience of the members with cooperatives.

Although usually it appears that the associations plan to operate on the Rochdale principle of one vote per member, one association states that its voting procedure will allow a member one vote for each room in the dwelling unit occupied.

Actual accomplishments.—In no case had any of the associations mentioned above actually built any dwellings by the end of 1946, although some of the organizations had been in existence for as long as 2 years. There were two reasons for this: restrictions on building materials, and uncertainty as to prices. In many cases, however, the association had bought land (ranging in those for which data were available from 100 to 253 acres) and others had taken options on sites. Some had selected architects or contractors, or both, and a few had gone so far as to obtain plans for a whole community lay-out.

Few were optimistic as to any early start on actual construction One association placed its construction date as the "summer of 194 or later," largely depending on construction costs, but in most case 1948 was regarded as more probable. The few exceptions were th veterans' groups which were counting on priorities and GI loans.

Federations.—A conference of housing cooperatives, held in Chicag in May 1946, authorized the formation of the National Cooperativ Mutual Housing Association. Organization was completed ju before the national Cooperative Congress in September 1946, and t association was represented at that meeting. It is expected that t federation will turn its energies to the exchange of experience, pro sion of technical service, accounting, training of project manage etc., leaving the handling of building materials to National C-operatives (the commodity organization) and its regional wholesal

The housing section at the Cooperative Congress presented a resolution, which was adopted, urging among other things that National Cooperatives establish a strong division for the procurement of building supplies,[2] and that the National Cooperative Finance Association organize immediately a program to make mortgage credit available to cooperative and mutual housing associations.

Structurally, the national housing association is expected to be a federation of regional associations, which will in turn be composed of State federations of local associations. Already one regional has been formed by the housing cooperatives in Indiana, Michigan, and Minnesota, under the name of North Central States Housing Association.

Provision of Medical and Hospital Care

Progress of local hospital associations.—From the Mississippi River westward, the spread of cooperative provision of medical care was outstanding in 1946. The greatest advance was in the formation of hospital associations. At the end of 1945 there were in operation six cooperative hospitals—one each in Florida, Kansas, Minnesota, and Texas, and two in Oklahoma. By the end of 1946, reports indicated that at least 9 cooperative hospitals were in operation and 13 associations were known to have been formed and under way. At least 22 others were in process and some of these had received charters, but data as to their exact status at the close of the year were not available.

In October 1946 ground was broken in Sandpoint, Idaho, for the first unit of a $100,000, 17-bed community hospital, on a 3½-acre plot near Lake Pend d'Oreille. The 725 members hoped to have it in operation by the summer of 1947.

Of the other associations concerning which progress reports are available, the association at Ely, Minn., reported pledges of $38,000 from 300 persons in October; it planned to remodel a former school building. At Fosston in the same State, the association had incorporated and elected its board of directors; no data were available as to membership or funds. In Greenbush, Minn., money was being raised for a 20-bed cooperative hospital. The hospital at Two Harbors, which started operation as a cooperative in November 1944, announced in 1946 its intention of establishing a small branch hospital at Grand Marais, 85 miles eastward on the north shore of Lake Superior.

The purchase of a 10-bed hospital by a cooperative association with members in two counties in Missouri—the first of its kind, known to the Bureau, in that State—was reported at the end of the year.

In South Dakota, cooperators at Leola had raised $18,000 toward the erection of a 20-bed building after only a week's work in November

---

[2] National Cooperatives stated in a letter to the Bureau of Labor Statistics, dated December 12, 1946, that it was already getting under way with the expansion of its facilities in this field.

1945; no later report has been received. In Winner, in October 1946, the Farmers' Union and local farmers' cooperatives were reported to be sponsoring and supplying organizing funds for a $100,000 cooperative hospital. The organization, Rosebud Cooperative Hospital, Inc., had already been formed, and 243 paid-up members, each contributing $100, had been obtained.

In Texas, over a score of hospital associations had been formed under a 1945 law authorizing their formation in places of less than 2,500 population. At Friona, by September 1946, 500 persons had joined a cooperative hospital association and had paid in $100 each toward the construction of a 30-bed hospital. At Olton plans were being made to remodel the building formerly used as a county courthouse. Construction of a hospital was under way at Rising Star, where a membership of over 700 had been obtained. The cooperative wholesale at Amarillo has been giving some assistance to these groups.

In most places the hospitals have been organized in rural districts which have previously had little or no medical or hospital facilities. In Washington State, however, urban industrial workers as well as farmers have been behind the organizing drive that has been going on for the past 18 months. The regional cooperative wholesale, Pacific Supply Cooperative, has had a full-time "cooperative hospital field counselor" at work throughout Idaho, Oregon, and Washington. In Seattle, Group Health Cooperative of Puget Sound was formed in 1946, with widespread community support including that of various local labor organizations, State and local Granges, and cooperative associations. Among the labor organizations were the boilermakers, milk-wagon drivers, aircraft mechanics, and Renton Central Labor Council. The members of the 1946 board of directors of the association included a representative each of the aircraft mechanics and boilermakers, a representative from each of four local consumers' cooperatives (one a students' cooperative at the State University), two Grange representatives, and a local businessman.

In November the association, which had originally planned to buy a surplus Government hospital at Renton, announced that it had merged with a doctor-controlled organization, the Medical Security Clinic. The latter was operating a 60-bed hospital and a large downtown clinic, with a staff of 18 physicians, and was providing prepaid service for some 7,500 members. Not altogether satisfied with private group practice, the clinic management had sent its manager to attend the conference of health cooperatives at Two Harbors, Minn., in August 1946.

His report and the months-long conferences that followed, with representatives of Group Health Cooperative, resulted in the decision to become part of the latter group. According to the manager—

> Frankly, the ideas presented came as a pleasant surprise to most of us, for we quickly recognized that cooperative medicine closely paralleled what we had been

> talking about, that we needed only to change names, rather than thought or intent, to make our conclusions into a good co-op leaflet. Cooperative medicine from the doctor's viewpoint, as I see it, means this: (1) A working arrangement which guarantees that no person, no thing, no corporate set-up, or sets of bylaws, comes between the doctor and his patient. * * * (2) Protection of the new doctor from exploitation. * * * (3) Provision of working conditions which offer financial security and stimulate the highest type of professional activity.[3]

Membership in the association costs $100. Monthly dues are $3 per month for an adult; $1.50 each for the first two children; maximum family charge, $9.00 per month. For these amounts the association will give the following: (1) Care in the home, clinic, and hospital, plus coverage while traveling, (2) prescriptions filled for members, without extra charge, in the pharmacy owned and operated by the clinic, (3) X-rays as ordered by staff physicians, (4) laboratory procedures required in diagnosis, (5) physical therapy treatments, and (6) vaccinations and inoculations. The association plans to add also a dental-care department which will operate on a cost-plus basis. Economic security for the staff is provided under an arrangement (financed equally by the association and the doctors) by which a physician retiring at 65 after 35 years' service receives a retirement payment of $25,000. Each year one-fourth of the annual net income of the association is to be paid to the medical staff, and an equal amount to the other employees.

Olympic Cooperative Hospital Association, at Sequim, and Kitsap Cooperative Hospital Association, at Bremerton—both on the Olympic Peninsula—were negotiating for hospital buildings at the close of the year, and a new association had been formed at Deer Park.

In Oregon the Community Hospital Association in Hermiston reported over 250 members in October, and the Salem Community Health Association sponsored by the Farmers Union had about 500 members. At Newberg an organizing drive was getting under way late in the year.

Cooperators in Wisconsin have made several attempts to organize cooperative hospitals, but have been blocked by the Wisconsin law which reserves to the medical profession the right to conduct prepaid group plans. The Wisconsin Association of Cooperatives—a State-wide organization of 214 cooperatives of all types (consumers', producers', and REA associations)—has pledged its support to an effort to amend the law so as to permit the formation of consumers' cooperative medical-care associations.

Prepaid medical care.—Group Health Association, Washington, D. C., which operates a clinic and pharmacy and which originally provided service for Federal employees only, early in 1946 adopted the open-membership principle on a "group basis," accepting Negroes as well as whites. Among the new groups reported as admitted under the new policy were employees of the local consumers' cooperative (an association operating 6 stores in the District of Columbia and Virginia), those of the Farm Bureau insurance companies, and those of the National Council of Farmer Cooperatives. The association also purchased a site of some 20,000 square feet on which it plans to erect a medical center.

---

[3] Quoted in Pacific Northwest Cooperator (Walla Walla, Wash.), November 1946.

Health insurance.—Among the associations providing cash benefits to meet the cost of medical and hospital care, Group Health Mutual of St. Paul, Minn., had a total membership of about 45,000 persons in April 1946. It added to its previous services a combination plan with benefits ranging from $5 to $200 for surgical cases, obstetrical benefits up to $60, ordinary hospital benefits up to $4.25 per day, and special hospital benefits up to $50. Among the new groups being served by the end of the year was the personnel of Pacific Supply Cooperative, in Idaho, Washington, and Oregon.

Medical-care federations.—Although cooperative medical care is still in its infancy, steps toward federation have already been taken. In the spring of 1946, six associations on the Pacific Coast formed the Northwest Cooperative Hospital Federation, to coordinate their educational and promotional work.

A Nation-wide conference of health cooperatives was held in August 1946, at which were present delegates not only from medical-care associations but also from labor and farmer groups interested in the provision of medical care. This conference authorized the formation of a national association, the purpose of which would be "to engage in educational and other activities for the promotion of the health and well-being of its membership and the public, and to carry on the following activities: (1) Educational, (2) advisory service in legal, management, technical, and organizational fields, (3) public relations and legislation, and (4) research in the field of medical economics." Adoption of articles of incorporation and bylaws for the new organization, the Cooperative Health Federation of America, was announced at the Cooperative Congress in September. At the same time a labor committee was formed, with headquarters in Washington, D. C., to foster the formation of prepayment medical-care plans; a small executive committee (including a representative of the medical profession) was elected to further the federation's work. A drive is to be made to obtain the affiliation of "all prepaid medical-care plans in which consumers have effective control." The previous federation, Group Health Federation of America,[4] formed in 1940, disbanded and turned its assets over to the new organization.

---

[4] It accepted into membership doctor-controlled as well as consumer-controlled plans.

Electric-Power Cooperatives

The Administrator of the Rural Electrification Administration reported, at the end of 1946, that for the first time in the 11-year existence of the REA, the outlook for the program was "grave" and that "horizons for rural electrification are shrinking."[5] This situation he attributed to the much greater cost of materials and construction and to the fact that the REA power lines are being extended into "leaner" neighborhoods with only 1 to 3 consumers per mile of line. In some cases the costs are so high as to preclude new projects from being self-liquidating. By December 31, 1946, some $957,000,000 had been earmarked or expended for loans. Of 1,008 REA borrowers, 929 were cooperatives, 39 were public power districts, 20 were other public agencies (mainly municipalities), and 20 were commercial power companies. Altogether, 1,549,057 consumers were being served by REA-financed systems at the end of June 1946, and only Connecticut and Rhode Island had no REA lines.

In Oklahoma, the citizens of one town are reported to have voted unanimously to sell the city-owned power system to a local REA cooperative, and a Kansas cooperative laid an 8-mile oil pipe line from adjacent oil fields to its generating plant. In Wisconsin, Dairyland Power Cooperative, formed by 19 Wisconsin and Minnesota REA cooperatives, purchased (subject to the approval of the Wisconsin Public Service Commission) privately owned properties including 8 hydroelectric plants, 470 miles of transmission lines, and 1,300 miles of distribution lines in the two States. Five electricity cooperatives n South Dakota late in the year bought out a private company, the purchase involving 2 generating plants and 256 miles of distribution ines. Other purchases planned or made were carried to the courts or administrative agencies for determination, being decided adversely in ome cases and favorably in others (see page 34). On the other hand, several REA cooperatives were reported to have sold out to private interests.

Insurance Associations

In Indiana the Farm Bureau Fire & Tornado Insurance Co. was aunched early in 1946, as the result of a poll among Farm Bureau members in 1945; at the end of its first 5 months of operation it is eported to have had $16,000,000 of insurance in force. The Hoosier arm Bureau Life Insurance Co., previously established, added to its enefits a group hospitalization and surgical expense benefit policy; y October 1946 the plan had gone into operation in 21 counties. arge gains in new business were also reported by the five companies perating under a unified system in Minnesota and Wisconsin, by the range life insurance association covering the northwestern States,

---

Rural Electrification News (Washington), January 1947, p. 2.

and by the Ohio Farm Bureau insurance companies (writing fire, life, and automobile insurance in 12 States and the District of Columbia). The Ohio companies in 1946 purchased their fourth office building in Columbus, to provide additional office space for the 1,300 employees there.

COOPERATIVES IN SPECIAL GROUPS

Students' Cooperatives

The year 1946 was one of revival of activity for the campus cooperatives furnishing rooms, meals, or both. The departure of the male students into the armed forces during the war years had resulted in seriously decreased membership and cessation of activities in many cases, only partially compensated for by some expansion of cooperative facilities for girl students.

As the young men returned from service into the educational institutions and new students entered for the first time, many of the former student associations were revived and new associations were formed. The greatest problem for the cooperatives was that of finding quarters.

Some strong associations solved their problem by purchase, either voluntary or because that was the only means by which a building could be obtained. On the Pacific coast the University of California Students Cooperative Association, which dates from 1933 and was already serving meals and operating six houses for students, bought a large residential hotel which, with furnishings, cost $125,000. The building and its interior garden covers nearly half a city block and is being used to house 150 women members of the cooperative. It was reported that the association had 655 members in October 1946.

In Seattle the Students Cooperative Association, whose 275 members attend the University of Washington, purchased two additional houses accommodating about 45 young men.

In Illinois the student cooperatives at the University of Chicago in 1945 formed a federation to perform various services for them. Early in 1946 this federation, United Cooperative Projects, bought a large house near the campus, accommodating some 33 roomers. The University of Kansas Student Housing Association, a central organization operating several rooming and boarding houses, bought a large house in Lawrence, formerly occupied by a fraternity. At Baker University, in the same State, the Men's Cooperative Club lost its quarters in a rented house. However, this informal group incorporated under the name, Students Cooperative Association, and bought a nine-room house, paying a rent which it is reported will amortize the purchase price in 4 years. Funds are being raised through the sale of stock to other cooperative associations in the area.

Other organizations were reported to be raising money with which to buy residences for their members. At North Dakota Agricultural College (Fargo), the revived student organization, NDAC Farmers Union Cooperative Association, launched a drive for funds with which to build a permanent residence hall. Funds were being solicited in the form of capital stock in the new venture, from Farmers' Union cooperatives and sympathetic individuals. The building is planned to accommodate 38 roomers and about 60 boarders.

As the students' necessity to economize is one of the major motivating factors in the establishment of campus cooperatives, lack of money is their chief handicap in becoming owners. Some of the associations, as noted above, are trying to solve their problem through incorporation (many have been simply informal groups) and the issuance of capital stock paying a fixed rate of interest. The stock is then offered to local cooperatives in the region and to individuals. Others suggest that financing could be done by an organization combining all cooperatives on a campus (as at the University of California, University of Washington, etc.) more successfully than would be possible for a one-house association.

Others are considering the long-term possibilities of a central revolving fund which could be used over and over to help finance various student cooperatives. This idea was advanced early in the year by the Central League of Campus Cooperatives, which had already raised some $2,000 for the purpose. It has since proceeded along this line, assisted by legal advice from the regional wholesale, Consumers Cooperative Association.

Federation for various purposes among student cooperatives has made a good deal of progress. On many campuses individual associations have formed a "cooperative council" for exchange of experience, pooled buying, and other activities.

A second step—the formation of federations of student cooperatives in a given area—was taken as early as 1938 with the establishment of the Midwest Federation of Campus Cooperatives. This was followed in 1939 and 1940 by the Pacific Coast Students Cooperative League and Central League of Campus Cooperatives, respectively.

The year 1946 saw the formation of the North Central Federation of Campus Cooperatives.

In general it is expected that the territorial coverage of the student ederations will correspond, at least roughly, with that of one or more egional wholesales. The Pacific League's membership would thereore consist of representatives from student cooperatives in California, Oregon, and Washington, and may include also those in Idaho, Nevada, and Utah. Midwest territory would cover Illinois, Indiana, Ohio, and Michigan. Central would include Arkansas, Colorado, Iowa, Kansas, Nebraska, Oklahoma, and Wyoming. North Central's territory would cover the Dakotas, Minnesota, and Wisconsin, and possibly Montana. No federations have as yet been formed for the Atlantic States (including Pennsylvania), for the Southeast, or the Southwest, although representatives from student cooperatives in Eastern Cooperative Wholesale territory (North Atlantic States and New England) have held conferences to discuss the possible formation of an eastern league.

The capstone to the student cooperative network was reached with the organization of the North American Students Cooperative League in 1946. To it the various regional federations and the newly formed (1946) Canadian Students Cooperative League are expected to affiliate. The Central League of Campus Cooperatives was the first to become a member of the new national organization.

The meeting at which the NASCL was formed was attended by representatives from six regional cooperative wholesales, National Cooperatives, and the Cooperative League of the USA. Their presence attested to the interest of the organized consumers' cooperative movement in the student cooperatives and their desire to foster closer relations. Headquarters of the national student federation are at the cooperative center in Chicago, where are also the offices of the Cooperative League and National Cooperatives.

Student cooperatives purchase their groceries and other supplies through the regional wholesales and the latter in turn assist them in organizing, with business advice, in legal matters, and in other ways. Several of the wholesales have helped to meet the cost of sending delegates to annual meetings of the student leagues. The possibility of careers in the cooperative movement for graduated members of student cooperatives was foreshadowed by the attendance of the educational director of Pacific Supply Cooperative at the 1946 conference of the Pacific Coast Student Cooperative League. According to report, he was there "to see to what extent the student cooperatives could be looked to for future leadership personnel." [6]

Practical knowledge of the operation of consumers' cooperatives was gained by 12 students, sponsored by the American Friends Service Committee, who during the summer of 1946 worked in cooperatives during the day, studied cooperation in the evening, and lived together on a cooperative basis.

Although most of the students' enterprises are run for the benefit of unmarried students, a large proportion of the enrollment at the various campuses consists of married ex-servicemen. For these, probably most of the universities and colleges have provided quarters either on the campus or adjacent to it. In numerous cases these veterans' families have also organized cooperatives, usually for the purpose of purchasing groceries. Some of these are limited to veterans; others are open to all the students, faculty, and staff. Veterans' cooperative stores are reported to have been formed at Alabama Polytechnic Institute, Iowa and Michigan State Colleges, the Universities of Florida, Kansas, Minnesota, and Wisconsin, and Texas A & M College.

---

[6] Co-ops on Campus (Chicago), September 1946, p. 2

Cooperatives of Other Groups

An Indian cooperative, formed in 1939 to market the baskets, beadwork, and other handcraft products of a group of Winnebago Indian families in Wisconsin, opened a cooperative grocery store at the beginning of 1946. The store's shelves were filled with "co-op label" goods bought from the regional cooperative wholesale. In New Mexico a new Indian cooperative store was reported at Ramah, and an official of the Albuquerque Consumers' Cooperative informed a representative of the U. S. Bureau of Labor Statistics that Indians at Isleta Pueblo had requested the cooperative to open a branch there. Chippewa Indians on a reservation in north central North Dakota started a cooperative general store which began business in September 1946. Only Indians on the reservation are to be admitted to membership, although any other persons may patronize the store.

As noted in previous reports, cooperative associations in the War Relocation Centers, established to house Japanese-Americans removed from the Pacific Coast during the war, at their peak did an annual business of some 10¼ million dollars. All these centers were closed at the end of the war and the cooperatives naturally lapsed with them. That some of the residents there have really absorbed the cooperative idea is indicated by reports in the Associated Cooperator (organ of the cooperative wholesale at Oakland, Calif.). One of the wholesale's fieldmen reported early in 1946 that in one farming locality in the San Joaquin Valley returned Japanese-Americans, together with Caucasians, had already formed one new consumers' cooperative and another (entirely Japanese) was in process of formation in another place. On the basis of his reports the wholesale voted to assign a worker to assist other similar groups that might wish to organize.

Developments Among the Federations

COMMERCIAL FEDERATIONS

Joint activities.—Two regional associations were admitted to membership in National Cooperatives in 1946: British Columbia Cooperative Wholesale (Vancouver, B. C.), and Tennessee Farmers Cooperative Association (Columbia, Tenn.). The latter is reported to be a federation of 30 farmers' marketing and purchasing cooperatives in the TVA region. The national organization, now a federation of 22 regional wholesales, voted to buy Cooperative Mills, at Auburn, Ind., a flour mill formerly owned jointly by a number of regional wholesales. The annual meeting of the association also authorized a national program for the production of lumber by National, to be financed by the member regionals and their retail members.

Coal rights on some 6,000 acres in Kentucky are reported to have been acquired by joint action of Indiana and Ohio Farm Bureau Cooperatives and Midland Cooperative Wholesale. A new association, the Millers Creek Coal Cooperative, was formed to mine the coal. Midland Cooperator reported (October 9, 1946) that the property was expected to provide about a fifth of the coal distributed by the three regionals. (Indiana Farm Bureau Cooperative Association already owned a majority interest in another mine in Kentucky.) Shortly afterward, the directors of Central States Cooperatives (Chicago) decided to join the above group and assist in financing it.

Three regional consumers' wholesales (Midland, Farmers Union Central Exchange, and Central Cooperative Wholesale) and a producers' marketing cooperative (Farmers Union Grain Terminal Association) cooperated in the formation of Northwest Cooperative Mills in 1945, to manufacture feed and commercial fertilizer. The grains used in the manufacture of the feeds will be supplied by the marketing association. By September 1946, it was reported that the new organization's headquarters building, feed mill, and seed-cleaning plant—all in the midway section of St. Paul—and a fertilizer plant at Green Bay, Wis., were nearing completion. Since its formation in 1945, Northwest Cooperative Mills has been operating a soybean plant originally owned by Farmers Union Central Exchange at Menomonie, Wis., and a small leased seed plant at Thief River Falls, Minn. Several of the regional wholesales joined in the formation (in February 1946) of the Central Farmers Fertilizer Co., with headquarters in Chicago.

It was reported in July that National Cooperative Refinery Association had, in the period October 15, 1945, through June 1946, drilled 37 producing and 9 dry wells. Several others had been drilled down to the oil sand.

A fire in August on its timber land adjacent to the International Lumbering Association's shingle mill in British Columbia resulted in the loss of some 2,000,000 feet of cut timber and much equipment. This caused a shut-down of operations for some time.

Cooperative Plant Foods (the members of which are Midland Cooperative Wholesale, Indiana Farm Bureau Cooperative Association, Wisconsin Cooperative Farm Supply Co., and Illinois Farm Supply Co.) completed the erection of a fertilizer-mixing plant and an acidulating plant in 1946.

A new service federation was formed in mid-1946 by the three local cooperatives in Lake County, Ill., to run an electrical-appliance store in Waukegan. Before the end of the year it had decided to open a furniture department. In Iowa it was reported that 19 local cooperative associations with a combined membership of 7,000 persons, had formed the Propane Gas Cooperative, to store and distribute propane gas (used for cooking, heating, refrigeration, etc.). This will be a boon in rural places and, as one report put it, will give the farm home "all of the advantages of city living."

Expansion by individual wholesales.—Associated Cooperatives, California, added to its previous services for local associations "management counsel" through a field supervisor, for the purpose of working with local boards to put their associations "on a sound businesslike operating basis." In May the wholesale announced its first management contract (containing a 90-day cancellation clause) with a local affiliate. The California wholesale, as previously reported, in 1945 adopted the policy (in places where no local distributive cooperative exists) of entering into agreements with local retailers to distribute its cooperative and dairy equipment. By July two dealers, one in Merced and one in Sacramento, had entered into such an arrangement. It is expected that these dealers "will cooperate * * * in the development of a cooperative program among the farmers in the area."

An accounting service for member cooperatives was started by this wholesale in September. A $65,000 warehouse in Oakland was purchased at the end of the year; a site at Emeryville, acquired in 1945 but never built upon because of inability to obtain authorization, is to be put up for sale. Following its announced intention of expanding into the building-materials field, Associated Cooperatives invested $15,000 in a lumber mill near Eureka, giving it purchase rights to the output. Its new building-supplies department was scheduled to start operations in January 1947.

In Chicago, Central States Cooperatives had an experience similar to that of the California wholesale, in failing to obtain permission to build on the land it bought early in 1946. Later, it acquired an existing warehouse and office building, but was unable to obtain possession from the company occupying it. Illinois Farm Supply Co. opened a fertilizer manufacturing plant in 1946.

The Indiana Farm Bureau Cooperative Association completed the conversion of its skimming plant to a cracking plant and the latter went into operation in May 1946. This step increased the daily gasoline capacity from 3,000 to 4,000 barrels and made possible the production of 80-octane gasoline from 60 instead of 28 percent of the crude oil. It was reported that the wholesale would thereafter be able to supply from its own refinery (which occupies a 20-acre tract near Mt. Vernon, Ind.) almost all the petroleum requirements of its member associations. In April this association was reported to have 72 producing oil wells. In addition to its three sawmills in Arkansas, the wholesale reports that it is also "financing and controlling" three in Mississippi. The feed mill at Hammond,[7] which the wholesale bought in the fall was severely damaged by fire shortly after it came into the possession of the wholesale.

A stock issue of $600,000 by Michigan Farm Bureau Services, to build a fertilizer-manufacturing plant, was oversubscribed. A large fertilizer factory with an annual capacity of 40,000 tons, was placed in operation by Minnesota Farm Bureau Service Co.

In the spring of 1946, Midland Cooperative Wholesale purchased 440 acres of oil-bearing land in Oklahoma, near its refinery at Cushing; the tract had 21 producing wells in operation at the time of purchase, yielding some 1,600 barrels of crude oil daily. Later in the year two producing wells were brought in, one in an area owned by Midland and the other on a 900-acre tract in which it owns a half interest A $15,000 addition to its oil-blending plant and office building in Minneapolis was authorized by the board of directors.

The Laurel (Mont.) petroleum refinery owned by Farmers Union Central Exchange (St. Paul, Minn.) was seriously damaged by fire in June 1946, but was able to resume partial operation almost immediately. In July it was reported that 4 wells had been brought in on the 200-acre tract the association had leased from the State for $39,000 in 1945 (300 acres adjoining were later acquired). These wells were producing between 65 and 75 barrels of crude oil per day. An oil-trade journal was quoted as predicting that the earnings from the 4 wells would retire the entire investment cost in 1 year. Other accessions to its facilities by the wholesale included additions to its warehouse at Great Falls, Mont., and the expansion of its headquarters in South St. Paul.

Consumers Cooperative Association (Missouri) made improvements at its lubricating-oil refinery valued at about $1,000,000 in 1946, designed to increase the productivity and make possible the recovery of by-products. During the first half of 1946, it purchased a lease on 300 acres in Kansas and a third interest (with two independent operators) on 1,860 acres in Oklahoma. The latter it will operate for the other two owners. With these acquisitions, the association reported, it had under its control nearly 100 square miles of oil-bearing land. At the end of its fiscal year (August 31, 1946) it had 448 producing wells, yielding 31 percent of its refineries' requirements; of these, 45 were drilled and 54 were purchased during the year and 19 were sold or abandoned. For the third successive year all of the needs of its affiliates for refined fuels were supplied from its own refineries and that of the National Cooperative Refinery Association.

---

[7] Formerly operated by the Farm Bureau Milling Co. (members of which were the Indiana and Wisconsin Farm Bureau Cooperative Associations, Michigan Farm Bureau Services, and Illinois Farm Supply Co.).

In December 1946 the wholesale announced the purchase of privately owned oil property in Kansas and Oklahoma, including 189 wells producing 70,000 barrels of crude oil per month and 20,000 acres of developed and undeveloped leases; also the purchase of a controlling interest in a Kansas company with 99 wells and 65,000 acres of oil leases. These additions increased the total number of wells owned or controlled by it to 736.

A new petroleum terminal at Watertown, S. Dak., was opened by this association in 1946. Since the end of the war the wholesale has resumed its overseas shipments, and its lubricating oil has been sent to eight countries (Australia, Belgium, China, France, Netherlands, Norway, Sweden, and Union of South Africa). Improvements to its sawmill at Swisshome, Oreg., increased its weekly capacity from 17 to 22 carloads; lack of railroad cars, however, was a continuing handicap throughout the year. The output of its cannery was expected to reach 350,000 cases (140,000 cases in 1944–45) as a result of adding numerous less-perishable commodities.

Eastern Cooperative Wholesale (New York City) bought a new and larger branch warehouse in Cambridge, Mass., increasing its space by about 93,000 square feet. Its annual meeting authorized the erection of a branch warehouse building on land already owned in Philadelphia and approved a program calling for addition of electrical appliances, and expansion of the departments handling household and automotive supplies and perishable and nonperishable groceries.

The Pennsylvania Farm Bureau Cooperative Association built a chick hatchery. Consumers Cooperatives Associated (Texas), which bought a petroleum refinery in 1945, purchased 24 producing oil wells in 1946, near Roswell, N. Mex., and Midland, Tex. Since the passage of the Texas cooperative-hospital enabling act in 1945, this wholesale has been assisting organizing groups to purchase equipment and supplies from the War Assets Administration. It has also made available to them lists of hospital equipment, estimates of costs, etc.

On the Pacific Coast, Pacific Supply Cooperative (Walla Walla, Wash.) and the newly formed Cascade Cooperative Wholesale took over a large building in Seattle which will serve as headquarters for Cascade and as a branch warehouse for Pacific. Pacific Supply Cooperative purchased two privately owned feed mills in central Oregon, bringing its total to three.

Central Cooperative Wholesale (Superior, Wis.) bought another warehouse in Superior and erected a branch warehouse in Escanaba, Mich., from which to serve cooperatives on the Upper Peninsula. Other expansion planned included a terminal at Wadena, Minn., and a lumberyard at Virginia in the same State.

NONCOMMERCIAL FEDERATIONS

Congress of the Cooperative League.—The most important cooperative event of the year was the national Cooperative Congress, held in September. This was a joint congress of the Cooperative League (educational body), the Cooperative Finance Association, and National Cooperatives (wholesale association). Its deliberations covered the whole range of cooperative effort in the consumer field; its sessions dealt with production, promotion, insurance, distribution, finance (including credit unions), housing, health, recreational, education, women's activities, young people's activities, personnel, relations with various groups (labor, churches, urban-rural, etc.), as well as international relationships and activities.

Among the more important actions of the congress were the following: (1) The transfer from the Cooperative League to National Cooperatives of employee training, general educational work, and publicity; (2) the transformation of the Cooperative League into a national organization, which would be a federation of national organizations in various branches of the consumers' cooperative movement (distribution of commodities, credit, electricity, insurance, medical care, housing, and recreation), to carry on research, statistical, and public-relations work; and (3) the passage of resolutions (*a*) urging the establishment of an international cooperative petroleum association, (*b*) requesting the International Cooperative Alliance to establish a branch in the United States, (*c*) declaring "full and unqualified support of the entire United Nations effort," and (*d*) favoring the establishment of a permanent Inter-American cooperative educational institution with branches in North and South America. A meeting of the board of directors of National Cooperatives, previous to the Congress, established as policy that in future all production on a national scale is to be carried on by National Cooperatives. Action taken by the congress on other specific subjects is here noted under such subjects.

A new association, Arizona Cooperative Association, whose first activities, it is reported, will be in writing insurance and making small loans, was admitted to membership in the League in 1946.

Other educational federations.—The past 2 years have seen the formation of many noncommercial federations. Some of these have been formed mainly as a means of defense against attacks such as those made by the National Tax Equality Association,[8] others to provide a clearing point of experience for existing cooperatives, and all to provide educational service and materials.

---

[8] State-wide councils for this purpose exist in Colorado, Iowa, Kansas, Missouri, Montana, North and South Dakota, Nebraska, Wisconsin, and Wyoming. These in turn are federated in the National Association of Cooperatives, formed in 1944.

Following the example of certain other States, cooperatives in Minnesota early in 1946 formed the Minnesota Association of Cooperatives—a State-wide association for all types of cooperatives. Its announced purpose is to "present a united front in advancing and defending the interests of cooperatives of all kinds," provide "research, public relations, and educational services," and act as a clearing house on matters of common interest.

State or regional educational federations of consumers' cooperatives have already been formed for Connecticut, the D. C.-Maryland-Virginia area, New England, and New Jersey. Many federations have also been established, covering a metropolitan area, one or more counties, or other regions of less than State-wide coverage. Many of these also are not limited to any one type of association but seek to embrace and to forward the interests and expansion of all cooperatives in their area, promoting their understanding of each other's problems and providing mutual assistance.

In addition, several of the regional wholesales have been encouraging the formation of educational federations throughout their trading areas. It is pointed out that such federations are valuable in increasing the members' knowledge of cooperative principles and aims, in arousing and sustaining the membership interest, in carrying on drives to increase cooperative membership and business, in arousing cooperative interest among young people, and in fostering better public understanding of cooperatives.[9] In May 1946 Consumers Cooperative Association announced the formation of six such federations, and a seventh was being organized; these included three in Colorado, one in Iowa, two in Kansas, and one in Missouri.

In the territory of Midland Cooperative Wholesale several educational federations have been started in Minnesota and Wisconsin, and Central Cooperative Wholesale announced the establishment in September of a federation for Western Minnesota. In Ohio the Farm Bureau Cooperative Association has been fostering the formation of small discussion groups or "advisory councils," with great success. As of September 1, 1946, there were 1,385 such councils, the main purpose of which, it was stated, was to "make democracy work." The agenda of these councils therefore covers practically all subjects (including cooperatives) affecting the life and welfare of the people.

The new federations of students', medical-care, and housing cooperatives have already been mentioned (pages 6, 10, and 14).

---

[9] Cooperative Consumer (Kansas City, Mo.), May 15, 1946.

Problems of Organization and Structure

ON THE NATIONAL LEVEL

A proposal for the merger of the Cooperative League, National Cooperatives, and the National Cooperative Finance Association has been under consideration for several years. The boards of the three organizations had approved a single executive for the three and established a joint committee to work out the details of consolidation. At the national Cooperative Congress in September 1946, after many protracted meetings during the year, the committee presented a surprise report and recommendations which differed completely from previous plans. Briefly, it proposed that, instead of a merger, National Cooperatives would become the national organization for the distributive branch of the cooperative movement, .combining commercial activities with educational and publicity work and therefore taking over Rochdale Institute, the Co-op Magazine, Cooperative News Service, and national employee training, all of which had previously been departments or functions of the League. The latter (which celebrated its thirtieth birthday in March 1946) would carry on research, compile statistics and other information, and do public-relations work on an over-all basis. It would become the national organization of all branches of the consumers' cooperative movement in this country—distributive, electricity, credit, insurance, housing, medical care, etc.

The report and recommendations were accepted by the congress, after considerable discussion.

Unlike the situation in many European countries, in the United States each branch of the cooperative movement has developed independently. The REA cooperatives, credit unions, student cooperatives, medical-care associations, and distributive associations each have their own national federation. The federations in the fields of housing, medical care, and provision of meals and rooms for students have only recently been formed and have as yet no great accomplishments to their credit.

The Credit Union National Association ("CUNA") became a fraternal member of the Cooperative League in 1939, and the Cuna Supply Cooperative became a full member in 1942. The affiliation of the latter (a commodity organization) probably will hereafter be through National Cooperatives. The new federations of students' associations and of housing and medical-care cooperatives undoubtedly will affiliate with the League, but no relationship has as yet existed with the REA cooperatives; their affiliation has still to be won. No national insurance federation exists, though some of the most powerful of these associations have been consistent financial supporters of the the League.

It appears, therefore, that the solid underpinning of the League at present consists of only the distributive movement and these insurance organizations. Support from the other branches either consists largely of good will or has still to be won. Undoubtedly the new structural plan offers a much wider scope for the League than before, if the latter is successful in rallying to its banner the various service branches of the movement.

ON THE REGIONAL LEVEL

The 1946 annual meetings of Eastern Cooperative League and Eastern Cooperative Wholesale approved a committee draft of a constitution and bylaws of a proposed consolidation of the two that has been under way for some time. The name of the new organization is Eastern Cooperatives, Inc.

In the territory of the above organization, which serves local cooperatives on the whole eastern seaboard as far south as Virginia, a move among some of the New England associations to secede and form a separate wholesale for that region was under study during 1946. The report of a committee, appointed in conformity with instructions from a membership meeting in February, was laid before a special meeting held in September 1946. The committee recommended the establishment of a separate wholesale. Debate at the meeting covered the possible deleterious effects of such a move on the unity of the cooperative movement in the East, and the difficulty of financing a new wholesale. The meeting decided to postpone action until April 1947, with an enlarged committee gathering more facts in the meantime.[a]

Among the district federations, Cooperative Services, Bruce Crossing, Mich. (handling petroleum products), voted to merge with Copper Country Cooperative Enterprises (a fish-marketing organization that evolved out of a self-help cooperative started during the depression). This action caused some threats of withdrawal of associations that were members of Cooperative Services; no information is available to indicate whether action was actually taken.

Education, Recreation, and Publicity

Realizing that the foundation of a sound cooperative movement is an informed membership, well grounded in the cooperative philosophy, and that well-trained efficient employees are essential to the financial success of the organizations, the cooperative movement lays great stress on educational work directed to both these requirements.

Education.—The central educational organization of the consumers' cooperative movement is Rochdale Institute, established in New

---

[a] At the April meeting the proposed separation was rejected, but with a recommendation of greater independence of action for the Cambridge (Mass.) branch warehouse of Eastern Cooperative Wholesale.

York City in 1937 and moved to Chicago in 1944. Provisionally chartered by the University of the State of New York in 1938, it received an absolute charter from that institution in 1945. In 1946 it held two short-term institutes—a 2-week course for educational directors, and a cooperative and labor institute sponsored jointly by the Wisconsin School for Workers. It also offered an 8-week course in the history, philosophy, methods, and practices of cooperation designed for those seeking employment in cooperatives, those already working in cooperatives, and "teachers, ministers, social workers, and co-op lay leaders" wishing to inform themselves about the cooperative movement. At the 1946 Cooperative Congress the director of the Institute reported that, during the 2-year period since the 1944 congress, the school had given 43 weeks of schooling to 436 students.

The Cooperative Correspondence School, initiated by Central Cooperative Wholesale in 1943 but now sponsored by six regional wholesales, continued in 1946 its courses in principles, practice, and administration and was reported to have an enrollment of over 1,000 students.

In addition, many of the regional wholesales themselves offer technical courses for cooperative managers and employees, and either alone or in cooperation with Rochdale Institute also offer advanced courses along the same lines. Under the auspices of Eastern Cooperative League and Wholesale, an institute for cooperative leadership was held in July–August, which also covered personnel matters, and housing. Under the same sponsorship a conference of educators and school administrators held earlier in the year discussed "education for democratic living." Central Cooperative Wholesale announced the inauguration of "membership clinics" to be held three times a year, to "discuss basic problems, train leadership, plan contact activity, and give an opportunity to exchange suggestions and ideas so that educational effort on the part of the locals and the Central Cooperative Wholesale will meet the greatly expanding requirements." In connection with the opening of a "co-op supermarket" in Lansing, Mich., a 4-session course in cooperation, open to public as well as members, was given.

During 1946 a score of students from South America came to the United States in a move sponsored by the Bolivarian Cooperative Union,[10] Rochdale Institute, Consumers Cooperative Association, the University of Kansas City, and the U. S. Farm Credit Administration. The training combined academic courses with actual work in cooperative enterprises.

Early in the year Midland Cooperative Wholesale created two annual fellowships of $1,000 each, for graduate study at the University of Minnesota in the fields of "business administration and economics, particularly agricultural and consumer economics."

---

[10] A federation of cooperatives in Bolivia, Colombia, Cuba, Panama, Peru, and Venezuela.

Among the general educational institutions of the country, several were reported to have included cooperative subjects. Cornell University was said to be giving a course in cooperative law, Harvard University continued its course in consumers' cooperation (given for a number of years in cooperation with the New England Cooperative Federation), and the University of Kentucky offered a short course for cooperative officials. The Cooperative and Labor Institute held at the School for Workers of the University of Wisconsin was attended by both CIO and AFL unionists.

A number of cooperative nursery schools—some of which were started in 1946—have come to the attention of the Bureau, mainly in the metropolitan area of Washington, D. C., and in and around Chicago. There are probably many others not known. The advantages of these schools, it is said, are that they provide the children with excellent preschool experience and afford their parents an opportunity to work with and observe training procedures under trained teachers and to participate in a nonprofit, cooperative enterprise.

Recreation.—In the cooperative movement, education and recreation usually go hand in hand, in that each generally contains elements of the other. In various places throughout the United States, local or regional cooperatives sponsor cooperative parks or camps as vacation spots for cooperators and their families; in connection with these, lectures, movies, etc., are usually given which provide information on cooperatives. Several of the regional wholesales also give courses for recreational leaders, in a vacation setting. In addition, the Cooperative Society for Recreational Education each year for a decade has conducted a national recreation school for persons training as cooperative recreation directors. The 1946 school was reported to have drawn the largest enrollment in the history of the organization.

Among the vacation events of 1946 was an auto caravan of cooperators which toured the cooperatives of Saskatchewan and Manitoba, Canada, and several centers in North Dakota, Minnesota, and Wisconsin. In Philadelphia, a "consumers' cooperative theater," Philadelphia Civic Theatre Cooperative, to be operated "for and by Philadelphians of all ages, colors, and beliefs,"[11] was started.

Publicity.—Cooperators have for some years been using radio as a means of spreading their message. In August the Federal Communications Commission granted the Potomac Broadcasting Cooperative (Washington, D. C.) permission to construct its own FM (frequency modulation) radio station. The new cooperative will operate in the DC-Maryland-Virginia area. It will issue both common and (nonvoting) preferred stock, the former to be held by cooperatives in the area, the latter to be offered to individuals and nonprofit organizations. It is reported that an application for an FM license was also made by the Connecticut Cooperative Federation.

---

[11] The Cooperator (New York), October 11, 1946.

Relationships with Other Groups

WITH LABOR ORGANIZATIONS

Closer relationships between the cooperatives and organized labor developed during 1946, continuing a movement that has been under way for a number of years. At the 1946 AFL convention the report of the Federation's executive board noted "significant progress in strengthening the ties between the AFL and the Cooperative League of the USA." It said, further:

> We commend the growing interest in consumers' cooperation which is developing among our unions. We urge all affiliated unions to take an active part in the consumer cooperatives in their communities, and where there are no well-managed cooperatives, to organize them.

At the 1946 Cooperative Congress the United Auto Workers (CIO), in a speech by its president, pledged its support in a strong drive to organize consumers' cooperatives in all communities in which it has locals. This is to be done through a series of advisory committees composed of key UAW and cooperative staff members. A month later the first full-time worker under this arrangement was appointed for the Michigan area. UAW workers were reported as being active in the organization of cooperatives at Detroit, Flint, Iron Mountain, Jackson, Lansing, and Pontiac.

The Minnesota State Federation of Labor, at its 1946 convention, adopted a resolution urging all the local unions to appoint committees on cooperatives. Its public relations department will assist these committees in informing the union members about the cooperative movement. In Massachusetts the State Federation of Labor appropriated from its treasury money to pay the tuition of 10 unionists in the course in cooperation offered by the Massachusetts Department of Education. The Federation has for a number of years joined with the New England Cooperative Federation in sponsoring a course on cooperatives given by Harvard University.

Individual local unions are also reported to be actively supporting the organization of new cooperatives in various places. Among these reported as in process of formation in 1946 were cooperatives in Iron River, Mich. (iron miners, CIO), Negaunee, Mich. (miners and steel workers, CIO), Eveleth, Minn. (iron miners and other unionists), Borger and Crane, Tex. (oil-field workers' union), Burlington, Vt. (auto workers, CIO), and Everett, Wash. (aircraft and other unionists). In Arizona, AFL unionists are said to have sponsored the new Arizona Cooperative Association, recently admitted into membership in the national Cooperative League. In Connecticut a CIO union is reported to have turned over the first floor of its building to accommodate a new branch store opened by the local cooperative.

Several successful labor-cooperative conferences were held in 1946. The resolutions of one of these, held in Milwaukee in September, indicate the scope which such conferences may cover. These resolutions urged cooperative and union assistance for the new national housing and health cooperative federations and the formation of union-sponsored health plans in Wisconsin, recommended the formation of credit unions by every trade-union and cooperative, and endorsed the Wagner-Ellender-Taft housing bill. A labor-cooperative conference in Minneapolis, attended by representatives of AFL, railroad, and CIO unions, resulted in the establishment of a permanent labor-cooperative council for the furtherance of urban cooperatives. Plans were made for the exchange, through the Minnesota Association of Cooperatives, of labor and cooperative news among the periodicals of both groups.

There have been many instances, over the years, of cooperative aid to striking unionists. In 1946 several cooperatives gave aid to striking iron miners in Michigan, Minnesota, and Wisconsin. Among these were the cooperative oil and store associations in Rock, Mich., which donated $100, the small store in Ishpeming, which voted them half of the store's total earnings of $200, and the cooperative store at Wakefield, which gave $50. In addition, the annual membership meeting of Central Cooperative Wholesale (Superior, Wis.) voted to contribute $1,500, the district petroleum cooperative at Hurley, Wis., gave $200, and the Van Buskirk cooperative in the same State donated $100. The 3½-month strike was successful in winning the wage inrease and improved working conditions demanded by the workers.

In two strikes, Eastern Cooperative Wholesale reported that it had old directly to union representatives food supplies needed for their members which the strikers were reported to have been refused by ther wholesalers. Striking automobile workers in Toledo were reorted to have used the local cooperative as their commissary, spendng their strike-fund vouchers for co-op groceries.

The Fort Bragg (Calif.) consumers' cooperative contributed $100 er month to the relief funds of striking lumber workers.

Striking automobile workers received a carload of wheat from 10 embers of a Farmers' Union local in Montana—a step characterized y officials of the farmer and union groups concerned as "symbolic growing farmer-labor unity."

WITH CHURCHES AND CHURCH GROUPS

Several conferences of clergymen and cooperatives were held durg the year. Among these was one in Minneapolis in October, onsored by two regional cooperative wholesales and a grain-marketing cooperative, which was attended by ministers of many faiths as well as by representatives of cooperatives. Under the aegis of the Federal Council of Churches of Christ in America regional meetings on "the church and labor in consumers' cooperation" were held in Columbus (February), Baltimore (April), and Seattle (December). These meetings reaffirmed the Council's endorsement of the cooperative movement and the wish to "encourage the extension of cooperative techniques and other similar means of bringing about economic justice and brotherhood." The annual meeting of the Unitarian Fellowship for Social Justice, held in May 1946, adopted a resolution urging the American Unitarian Association to consider transferring its investments to consumers' and producers' cooperative enterprises.

It was reported [12] that Pope Pius XII, in a message to a conference of French Catholics in Strasbourg, France, advocated the formation of cooperatives in preference to nationalization of industry, declaring that "the cooperative form of economic life is more conformable to the teachings of Christianity, notably in what concerns human personality, the working community, and private prosperity."

CONSUMER-FARMER RELATIONSHIPS

There were numerous indications, during 1946, of the increasing desire of urban dwellers and farmers to come together on common ground. In various places in the Middle West, farmers and townspeople were working together for the establishment of new associations to run cold-storage locker plants, retail stores, electrical appliance and service businesses, etc. Meetings were held to explore new ways and means of working jointly for their common good. One such meeting, in Grand Rapids, Minn., in June 1946, was called by a committee representing the Farm Bureau, iron-ore miners, and paper-mill workers, assisted by a department of the cooperative wholesale at Superior, Wis. Another, in Minneapolis, in September, brought together 260 delegates from eight States, representing Farmers' Union locals, cooperatives, and AFL, CIO, and railroad labor organizations.

Several sessions of the 1946 meeting of the American Institute of Cooperation (an organization of farmers' cooperatives) were devoted to consumers' cooperative purchasing.

It has been the policy of cooperative associations sponsored by farm organizations (Grange, Farmers' Union, Farm Bureau, etc.) to admit to membership only members of the sponsoring group; some also practice the policy of check-off of farm-organization dues from any patronage refunds declared by the cooperative. Membership restriction is of course a violation of Rochdale principles. The explanation of the restriction in this case lies largely in the facts that these farmers' cooperatives in large measure owe their very existence to the educational work done by the parent farm organization, and that only in recent years have the farmers' cooperatives providing consumer goods and services identified themselves in any number with the consumers' movement that practices the Rochdale principles. It is also true of these cooperatives, as well as of those not connected with any farm organization, that they must restrict their membership to farmers if they wish to claim exemption from Federal income tax;[13] and they must meet certain membership requirements in order to borrow under farm credit laws. However, each year a number of the farmers' retail cooperatives (especially those sponsored by the Farmers' Union) adopt the open-membership policy.

---

[12] Cooperative News Service (New York), September 2, 1946.

One farmers' cooperative paper in Nebraska is advocating open membership on the grounds that a town family which patronizes the farmers' cooperative in sufficient volume to earn the price of a share of stock has shown its good faith and should be given a voice in its affairs, and that it is doubtful whether the small saving realized by a distributive cooperative through tax exemption compensates for the violation of cooperative principle.[14]

A tendency in the opposite direction is indicated in the recent movement of the farmers' marketing cooperatives into retail marketing of farm produce, not through consumers' cooperatives but through outlets owned by the farmers as producers.[15] Cooperative Producer and Consumer Family Foods, started as a department of the Cooperative G. L. F. Exchange at Ithaca, N. Y., in 1941, became an independent organization in 1944. By September 1946 it was operating 20 retail stores, of which 13 were of the supermarket type. In the fall of 1945, the Indiana Farm Bureau announced its adoption of a similar plan. Its first retail outlet was obtained by purchase of a privately owned supermarket in Veedersburg, Ind., in June 1946.

WITH EMPLOYEES[16]

The employee-retirement plan adopted by Midland Cooperative Wholesale in 1944 celebrated the end of its first year of operation in September 1946. This plan, financed by employee contributions of 3 percent of wages and association contributions of up to 5 percent of pay roll, initially covered only employees of Midland and of Central Cooperative Wholesale but was later opened to employees of affiliates of these two organizations. New members are accepted only at the beginning of each operating year. At the end of the first year 875 employees of 84 cooperatives were participating in the plan. At the beginning of October 1946, new adherents raised these numbers to 1,550 employees and 137 associations.

---

[13] Nonfarm cooperatives have no exemptions.

[14] Nebraska Cooperator (Omaha), July 17, 1946.

[15] See Bureau of Labor Statistics Bulletin 859, pp. 18–20.

[16] No study of collective agreements or round-up of changes in working conditions in cooperative associations was made by the Bureau. The information in this section therefore includes only the scattered items on this subject that came to the Bureau's attention.

Consumers Cooperative Association (Missouri) announced in July that it would start a similar plan for "workers in regional and local cooperatives throughout the Middle West," beginning September 1, 1946. Retirement age under the plan will be 65 years. The scheme will be on a contributory basis—3¾ percent from employees, and from the employing cooperatives enough "to maintain the plan on a sound basis" (but not over 6 percent of pay roll).

A cost-of-living bonus, based on the U. S. Bureau of Labor Statistics' index of consumer prices, was granted to its employees by Midland Cooperative Wholesale. Under its plan the amount of bonus is determined quarterly in accordance with the rise or fall in the index.

Local associations in increasing numbers are adopting the policy of devoting a specified proportion of the association's earnings to paying bonuses to the employees, thus providing a direct incentive toward improved efficiency.

Associated Cooperatives of California in February 1945 put its warehouse employees on a 5-day, 40-hour week (previously 44 hours). Several months later these workers joined the International Brotherhood of Teamsters, Chauffeurs, Warehousemen and Helpers (AFL) and in July the wholesale signed a collective agreement with the local.

For a number of years Eastern Cooperative Wholesale has had an agreement with a local of the International Brotherhood of Teamsters. A sudden strike was called by the union at the end of January 1946, in the effort to enforce demands upon the Wholesale Grocers Association. Although the cooperative was not a member of that association, its employees were also called on strike. The cooperative stated its willingness to accede to whatever terms were obtained from the grocers' association, but requested that its trucks be allowed to operate, as had been done on previous similar occasions. Failing in this, the wholesale signed a contract granting the demands, but served notice that if more favorable terms were given by the union to the grocers' association, it would expect the same consideration.

Range Cooperative Services,[17] Hurley, Wis., at its annual meeting voted its employees an extra day of vacation for each year of service in addition to the one week already allowed. An extra week's vacation was also given by Greenbelt (Md.) Consumers Services, with the proviso that the time be spent at cooperative conferences, camps and training sessions, with the association also paying for transportation to these sessions as well as "75 percent of other minimum expenses."

---

[17] Until April 1946 the name of this association was Iron Cooperative Oil Association.

International Cooperative Relationships

International cooperative congress.—In the international field, the event that overshadowed all others was the congress of the International Cooperative Alliance (the first since 1937) held in Zurich, Switzerland, in October. It was attended by delegates from the cooperative movement of 20 countries (including 21 from the Cooperative League of the USA), observers representing the governments of 7 countries (including the United States), the Economic and Social Council of the United Nations, and the International Labor Organization. Among the resolutions passed by the congress were those—

1. Calling for the establishment of formal relationships between the Alliance and the cooperative organizations of agricultural production and the World Federation of Trade Unions.
2. Urging the International Bank to create an administrative unit for cooperatives and give them access to available sources of funds for reconstruction.
3. Favoring free trade among the nations.
4. Urging that the Atlantic Charter be implemented by placing under UN the control and administration of the oil resources of the world, beginning with those of the Middle East, "by and with the consent of the States involved, these resources to be administered in such a way that cooperative organizations can be assured of receiving an equitable share."
5. Favoring cooperative representation in government bodies concerned with the economic and social policies of the State.

The predominant theme of the congress was the furtherance of cooperative international trade. At a conference preceding the congress it was decided that the International Cooperative Trading Agency should absorb the International Cooperative Wholesale Society.[18] International machinery to deal in petroleum products, either as a separate agency or as a department of the Trading Agency, was first proposed at the congress of 1937. No action was taken, however, as only a start in such trade had been made—by one regional wholesale (Consumers Cooperative Association) in the United States—and the time did not seem propitious.

Shortly after VE-day, a national petroleum cooperative was organized in Sweden, which immediately placed a large order for lubricating oil with CCA. In 1946 Norwegian cooperatives formed a petroleum association, and a few months later the Cuban movement did likewise. In order to expedite its shipments, the Swedish association in 1946 bought a 13,500-ton oil tanker which is being used to transport to Sweden its purchases of motor oil produced by the CCA refinery.

---

[18] The Wholesale Society, established in 1919, had never carried on any commercial activities but was simply a medium of exchange of experience and information among the cooperative wholesales of the various countries.

The 1946 congress of the International Cooperative Alliance completed the organization of the International Cooperative Petroleum Association, the formation of which had been approved in principle by a meeting of representatives of the International Cooperative Alliance and the International Cooperative Trading Agency in September 1945. It was specified that the new association would not come into existence until 10 central organizations had signed up for membership and at least $500,000 of its authorized capital of $15,000,000 had been subscribed. However, it was reported before the end of the congress that cooperatives in 22 countries had indicated their intention to participate and that $900,000 in share capital had already been pledged. The headquarters of the new association are to be in New York City. Howard Cowden, president and general manager of CCA, to whose efforts the creation of the new association is mainly due, is to be its temporary manager.

United Nations.—In February 1946, the General Assembly of the United Nations confirmed the bestowal of permanent consultative status for the International Cooperative Alliance in the Economic and Social Council. Murray Lincoln, president of the Cooperative League of the USA, was appointed by the ICA as its representative at the sessions of the Council in May 1946.

Cooperative relief measures.—Late in 1945, 22 relief agencies in the United States formed a nonprofit cooperative organization for European relief. These agencies were later joined by 3 others. They included the American relief agencies for 7 different countries, the welfare organizations of 7 religious faiths (Catholics, Quakers, Jews, Christian Scientists, Congregationalists, Unitarians, and Churches of Christ), representatives of AFL and CIO unions, the Cooperative League of the USA, and various other relief organizations. The new organization, Cooperative for American Remittances to Europe (CARE), soon got under way. Its packages of food, according to a report made at the 1946 cooperative congress in September, were then being shipped to 11 countries of Europe, the governments of which have agreed not to levy duties or taxes upon them. The cooperative reserves the right to designate the agency within each country which will act as distributor. In France, Finland, and Poland the cooperatives are so designated. In Norway the cooperatives have assisted in the distribution. By September 1946 CARE had shipped some 4 million dollars' worth of food to Europe, the money for which was donated by individuals and groups in the United States. "Patronage refunds" totaling 50,000 $10 packages of food were declared on the 1946 operations of the organization; in this case, however, the "patrons" were not the donors of the packages but the needy in Europe, who received this extra amount of relief. The president of CARE is the president of the Cooperative League of the USA.

In 1944 cooperatives of various countries started the so-called "Freedom Fund" for the rehabilitation of cooperatives in war-devastated areas. About 1¼ million dollars was raised, of which cooperatives in the United States contributed nearly $93,000. Of the latter sum, $15,000 was invested in CARE, with an additional $15,000 loaned for one year, and $5,000 was appropriated to defray the expense of bringing young Italian cooperative leaders here for study of United States cooperatives. Cooperatives in France, China, and Austria had been aided from the general fund.

Laws and Decisions Affecting Cooperatives

STATE LEGISLATION

Few State legislatures met in 1946. Among those which enacted legislation relating to or affecting cooperatives, the Kentucky Legislature authorized (ch. 51) the formation of nonprofit medical-service plans, the services of which are "administered by doctors of medicine." In order to operate, such corporations must receive a certificate of "convenience and necessity" and be adjudged in the public interest; must have the participation of 51 percent of the eligible licensed doctors in the county, and (although specifically exempted from insurance laws) must deposit a surety of $10,000 with the Custodian of Insurance Securities. The above conditions would probably prevent the operation of a cooperative having its own clinic.

In New York, chapter 787 added a new section to the cooperative law, authorizing the dissolution, by proclamation, of cooperatives that have failed for 3 consecutive years to file required reports with the commissioner of agriculture and markets. Such delinquent associations are given a 3-month period of grace in which to supply these reports, before actual dissolution takes place; a fee of $25 is imposed on associations which take advantage of this period, for the issuance of a certification of compliance and a fee of $40 for filing such certificate. The law reserves to associations formed under the cooperative law the right to use the word "cooperative" or any modification or derivative thereof; by chapter 800 of the 1946 laws the word "cooperation" is also reserved for their use. Dental-care benefits are added (by chapter 548) to the medical-care and hospital-care benefits allowed to be provided by membership corporations or cooperative associations. Group Health Cooperative, organized under the cooperative law, is given specific authorization by chapter 675 to reincorporate under the membership corporation law, if within 6 months from the passage of the act (April 10, 1946) all its members vote to do so.

A South Carolina act (Act No. 417) authorized any 10 "leading and capable citizens" to form a nonprofit hospital-service plan on a prepayment basis. Such a plan must be maintained as a nonprofit "cooperative corporation" and must renew its license annually. The directors (not fewer than 9 nor more than 24) must include representatives of the participating hospitals, licensed physicians, and the general public.

DECISIONS AFFECTING COOPERATIVES

Funeral cooperatives in Iowa won a victory in May 1946, under a decision by the State supreme court. It held, in *State of Iowa* v. *Winneshiek Cooperative Burial Assn.* (22 N. W. (2d) 800) that the cooperative association in the case was properly organized under the Iowa cooperative law, as an association for the purpose of conducting the "mercantile business" authorized by that law; that embalming was a business and not a profession, and that an association with a licensed embalmer may carry on a funeral-service business without contravention of the statute against corporate practice of a profession.[19]

REA cooperatives.—Several court decisions were made during the year affecting electricity cooperatives. On the Pacific Coast, the effort of a private power organization to block an REA cooperative from building and operating an electric-power plant in Walla Walla County was rejected by the superior court. In Washington and Oregon, 13 public utility districts and a number of cooperatives formed Interstate Electric, Inc., for the purpose of purchasing the properties of a subsidiary of a holding company that had been ordered by Securities Exchange Commission to dissolve. The cooperative purchase was designed to prevent a proposed consolidation of the subsidiary with another of the same holding company. The cooperative contended that the consolidation would give the new company a monopoly over Bonneville power and impede the growth of public power distribution. Its contention was rejected by the Federal Power Commission as "lacking in substance," and approval for the merger was granted.

In the Middle West, the Wisconsin Public Service Commission denied the application of Badger Electric Cooperative to buy the properties of a privately owned hydroelectric company. The commission held that the cooperative (financed 100 percent by REA) violated the rule against 100-percent financing of utilities and that its bid was too high; the commission also challenged the cooperative's financial ability to service the 7-county area to be covered. Rehearing was denied, and later a suit by the cooperative for judicial review was dismissed by the circuit court of Dane County. In Iowa, a U. S.

[19] For review of previous actions, see Bulletins Nos. 768 (p. 3) and 859 (p. 23).

Supreme Court decision, reversing prior decisions by the Federal Power Commission and the Circuit Court of Appeals for the District of Columbia, opened the way for an Iowa REA cooperative to operate a hydroelectric generating station; the court held that permission of the State board (which had twice refused it) was not necessary, and application could be made directly to the Federal Power Commission (*First Iowa Hydro-Electric Cooperative* v. *Fed. Power Commission*, 328 U. S. 152).

The Minnesota Supreme Court upheld the right (disputed by a private power company) of a cooperative creamery to obtain power from an REA cooperative of which it was a member and of the latter to serve it; specific permission had already been granted by the village in which the creamery was situated and under whose franchise the private power company was operating (*Gen'l. Minn. Utilities Co.* v. *Carlton County Coop. Power Assn.*, 22 N. W. (2d) 673).

Decisions on taxation.—Several decisions helped to clarify the tax position of cooperatives in 1946. The Commissioner of Internal Revenue ruled that the patron to whom a patronage refund is credited must be notified of the credit by mail, as soon as possible after the refund has been declared. The U. S. Supreme Court, in a case not related in any way to cooperatives (*Comr. of Int. Revenue* v. *Wilcox et al.*, 327 U. S. 404) enunciated, however, a principle bearing upon the tax issue, that taxable income cannot "accrue from the mere receipt of property or money which one is obliged to return or repay to the ightful owner." In California, the U. S. Circuit Court of Appeals held that to claim exemption from taxation on patronage refunds there must be a legal obligation on the part of the association, made efore the receipt of the income, to return to the members on a atronage basis, all funds received in excess of the cost of the goods old" (*Amer. Box Shook Export Assn.* v. *Comr. of Int. Revenue*, 156 Fed. (2d) 629). In Ohio the Circuit Court of Appeals ruled that an lectric-power cooperative was exempt from taxation under section 01 (8) of the Internal Revenue Code, as a nonprofit organization operated exclusively for the promotion of social welfare" (*U. S.* v. *ickwick Electric Membership Corp.*, 158 Fed. (2d) 272).

Taxation of Cooperatives

Farmers' cooperatives meeting certain requirements as to memberip and nonmember business have exemption from Federal income x on amounts held in reserves and on interest paid on share capital; nfarm cooperatives pay taxes on both of these. Neither type of sociation is taxed on amounts returned in patronage refunds.

Largely because of charges of unfair competition by cooperatives, de by the National Tax Equality Association,[20] the Small Business

---

See Bureau's Bulletins Nos. 821 and 860.

Committee of the House of Representatives held hearings over a period of several months in 1945. Its first interim report [21] was issued in April 1946. In it the committee concluded that tax-exempt farmer cooperatives have a slight tax advantage in their reserve and interest exemptions but that consumers' cooperatives and nonexempt farmers' associations have no advantages not available to all types of competitive business; that, since the cooperative serves only as an agent for its members, to whom its income belongs, taxation of its income would "require a drastic change in the basic principles of our revenue laws"; that "there is substantial evidence to show that the cooperative movement operates as a very successful means of combating monopolistic concentrations and, as such, is a very healthy addition to the American economy"; and that "many of the most vocal opponents of cooperatives are themselves members of cooperatives and their firms engage as members in cooperative enterprises."

The principal recommendations of the committee were that a single Federal agency be authorized to compile statistics of all types of cooperatives; that the Bureau of Internal Revenue amend its regulations to require cooperatives to issue to each patron evidence of his equity; that farmers' purchasing cooperatives be restricted to the handling of farm production supplies; that the retention of refunds be limited to a period of 5 years; and that Congress act to provide a basis for establishment, operation, and federation of nonexempt associations.

This report was followed, according to the chairman of the Committee, by a flood of letters to Congressmen from small businessmen, "on a scale rarely encountered." A statement issued by the Committee early in June 1946 reiterated the belief that cooperatives, far from being "a threat to the free enterprise system," are actually "an integral part" of that system and "a powerful means of combating monopoly."

Numerous decisions of the courts and of the U. S. Tax Court have held that amounts returned in patronage refunds are not taxable income to the association. Some representatives of profit business seem to agree with it. Thus, a representative of the National Association of Manufacturers, in an address delivered before the Indiana State Grange, expressed the opinion that there is "no justification" for "taxing at the source patronage refunds paid to customers of cooperatives," but he believed that amounts not so distributed should be taxed as earnings.

During 1946 several court decisions relating to taxation, involving or applicable to cooperatives, were delivered (see page 35).

Attitude of farmers' cooperatives.—One of the farmers' papers has expressed the view that the tax exemptions of farmers' cooperatives could be eliminated without hurting the associations. It pointed out that nearly half do not now claim exemption, preferring to operate on an open-membership basis,[22] and that, actually, "the growth of cooperatives is impeded by having exemption." [23] The Illinois Agricultural Association, in its 1946 convention passed a resolution supporting changes in the Internal Revenue Code and regulations that would provide tax exemption for agricultural cooperatives "on only that portion of their earnings which is distributed to their members or patrons." [24] Late in the year the National Association of Cooperatives formulated its own recommendations. It proposed legislation recognizing that all forms of business have an equal right to exemption on patronage refunds, taxing refunds retained in the business without the patron's authorization, allowing exemption on dividends or interest on share capital only as to amounts actually paid therefor "at the specially limited rates set up in the law," and requiring all cooperatives to file income-tax returns and to report each patronage refund of $100 or more. No prediction can, of course, be made as to what if any action on the subject will be taken in the 80th Congress which convened in January 1947.

LETTER OF TRANSMITTAL

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., July 7, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on the employment outlook in hotel occupations. This is one of a series of occupational studies conducted in the Bureau's Occupational Outlook Division for use in vocational counseling of veterans, young people in school, and others interested in choosing a field of work.

The report was prepared by Herbert L. Gottlieb, under the supervision of Helen Wood. Sylvia K. Lawrence assisted in the library research.

The Bureau wishes to acknowledge the generous assistance received in connection with this study from the American Hotel Association, the Hotel and Restaurant Employees' and Bartenders' International Union, AFL and the U. S. Employment Service.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

EMPLOYMENT OUTLOOK IN HOTEL OCCUPATIONS

Introduction

Inn-keeping had its beginnings more than 2,500 years ago, with the growth of trade and travel in the Near East. In the days of the early Egyptians, Babylonians, and Persians, there were inns scattered along the main caravan routes. Inns dotted the highways which were built throughout the Roman Empire. With the fall of Rome, however, travel became unsafe and practically ceased in Europe, and the number of lodging houses declined until the late Middle Ages, when the revival of commerce brought a great new growth in the inn-keeping business. During the 1700's, large and elaborate inns were built in France, especially near the King's court at Versailles. These were the first "hotels." From that time on, hotels multiplied in Western Europe. It was in the United States, however, that the largest and most luxurious ones were built. Many of the new American hotels catered to people of moderate means as well as to the rich; therefore, the number of hotels increased more rapidly here than in any other country.

The typical modern hotel in this country is not simply a lodging place but a complex organization ffering many kinds of services to its guests—from roviding them with food and doing their laundry o helping them get theater tickets and make travel arrangements. Most hotels also have large rooms that can be rented for public or private gatherings. Conventions (which number about 15,000 in an average year in the United States) are frequently held in hotels. Other kinds of gatherings which often take place there are local business, fraternal, and professional meetings; concerts and lectures; private dinners, dances, and weddings; and trade exhibits, where salesmen display their wares to buyers.

To furnish these many different services, hotels employed about half a million workers in mid-1946, more than were employed in such important trade and service industries as drugstores or laundries. There are hotels and hotel workers in all parts of the country—in small villages, medium-sized towns, and big cities. Many resort hotels are in remote spots in the mountains, woods, and deserts, and on islands off the coast. A great many different kinds of workers are employed: for example, managers, clerks, skilled maintenance men, restaurant and kitchen workers, and housekeeping and service employees. The qualifications needed for these jobs are so varied that men and women with very different educational backgrounds, personalities, and skills can find jobs in the hotel industry.

The Hotel Industry

There are three main types of hotels—transient or commercial), residential, and resort.

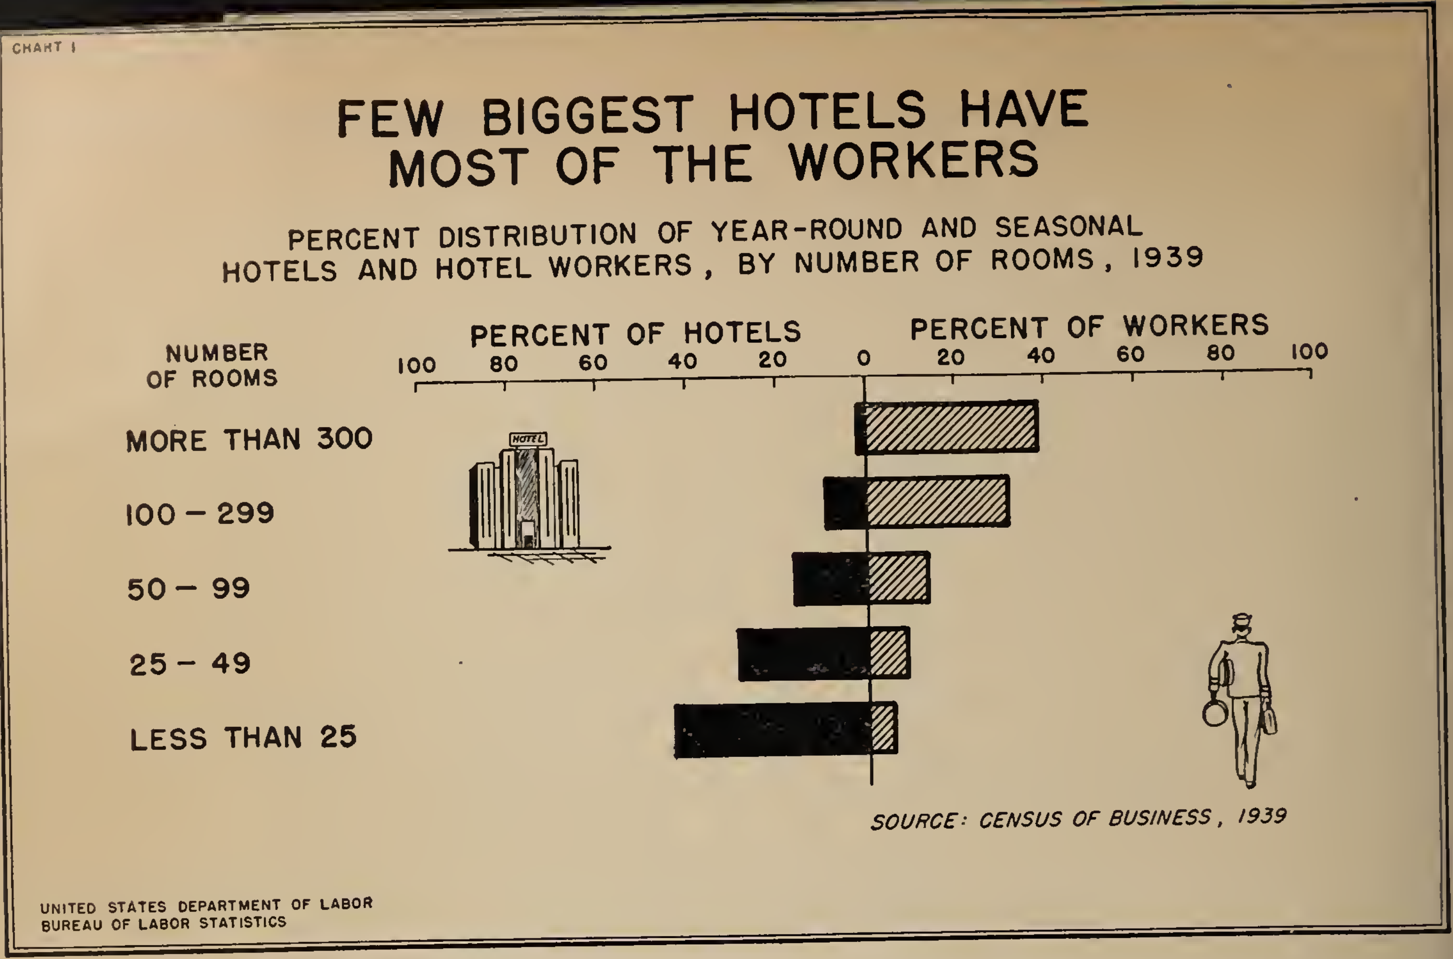
Commercial hotels are by far the most numerous pe, about three-fourths of the country's 28,000 tels being of this kind. Such hotels cater chiefly business travelers and tourists who seek lodging r short periods of time, though they may have me permanent guests.

Residential hotels, which make up less than one-nth of all hotels, let most of their rooms for relatively long periods. The rooms may be rented furnished or unfurnished and in some places housekeeping apartments are available, but "hotel service" is always provided. Commercial and residential hotels together employed about 322,000 workers during 1939, 95 percent of the average annual employment figure for the entire industry.[1]

---

[1] These figures do not include apartment houses or residential hotels catering exclusively to permanent guests.

CHART 1



FEW BIGGEST HOTELS HAVE MOST OF THE WORKERS

PERCENT DISTRIBUTION OF YEAR-ROUND AND SEASONAL HOTELS AND HOTEL WORKERS, BY NUMBER OF ROOMS, 1939

SOURCE: CENSUS OF BUSINESS, 1939

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Resort hotels cater to vacationers and are open for business only part of the year.[2] Some managers operate one hotel in the North and one in the South and move back and forth between them in the spring and fall, with all or most of their staff. Resort hotels represent about one-sixth of all hotels in the country. The number of people employed varies greatly from one season of the year to another: for example, in 1939, employment in such hotels was 13,000 in February, the busiest month of the Southern season; it fell to 8,000 in May, rose to 38,000 in August, the month when there are the most vacationers, and then dropped to a low of 4,000 in November.

The tremendous downtown transient hotels, some of which have over 1,000 rooms, are, in general, the largest ones, though some residential and resort hotels are very big also. In 1939, there were, altogether, about 3,000 hotels with more than 100 rooms; these employed 240,000 workers (see chart 1). In contrast, the 12,000 hotels with fewer than 25 rooms had only 20,000 employees.

The larger and more expensive hotels not only have more guests to serve but, as a rule, employ more workers per guest than smaller and less expensive establishments. A few big hotels have as many employees as guests, though the average for the industry as a whole is estimated at one worker to about every four guests.

There are some hotels in all parts of the country and nearly every city has at least one. However, the majority of hotel workers are employed in a relatively small number of States, resort hotel workers being concentrated in even fewer States than year-round hotel workers. Over three-fifths of the workers in year-round hotels in 1939 were employed in the following 10 States—New York, Illinois, California, Pennsylvania, Ohio, Texas, Michigan, Missouri, Massachusetts, and New Jersey. Of the workers in resort hotels, three-fifths were employed in only five States—two-fifths of them in Florida and New York and one-fifth in New Jersey, Maine, and California. Ten cities had over one-third of all the workers in year-round and resort hotels combined. These were New York, Chicago, San Francisco, Washington, Boston, Atlantic City, Los Angeles, Detroit, St. Louis, and Philadelphia.

---

[2] The Census of Business defines resort hotels as those open for business less than 9 months of the year.

Hotel Occupations

A great variety of jobs are to be found in the various departments of large hotels. In the executive department of a big hotel, there is likely to be a general manager, a personnel director, a publicity director, sales and advertising managers, and other executive and junior executive workers. The front office employs such workers as mail clerks, room clerks, reservation clerks, and the front-office manager. In the accounting department are auditors, bookkeepers, office-machine operators, cashiers, and other clerical workers. The housekeeping department includes not only the housekeeper and her assistants and the chambermaids but also housemen (who do heavy cleaning), furniture polishers, seamstresses, decorators, upholsterers, and others. Headed by the superintendent of service, the service department employs such workers as bellmen, baggage porters, elevator starters and operators, and doormen. The restaurant department includes chefs, cooks of various kinds, and kitchen helpers; the steward and his staff—pantrymen, storeroom employees, dishwashers; and waiters, bartenders, and other food and beverage service workers. In the maintenance department one finds such workers as stationary engineers, electricians, plumbers, carpenters, and painters. In addition, there may be auxiliary departments which employ, for example, laundry workers, barbers, valets, and tailors. Though small hotels do not have nearly as many separate occupations as this, practically all of them employ front-office, housekeeping, and maintenance workers, and some have restaurant workers and service mployees such as bellmen.

Restaurant and bar-room employees are the rgest occupational group in hotels, as shown in hart 2. In 1939, over one-third of the workers year-round hotels with more than 25 rooms were this group. One-fourth were housekeeping emloyees, more than one-tenth were employed in e service department, and another tenth were ngaged in front-office and other clerical work.

A number of occupations—including front-office erk and bellman—exist only in hotels. Each of ese typical hotel occupations is discussed separately in later sections of this bulletin. However, any of the occupations in hotels—for example, countant, carpenter, cook, waiter—are found also other industries. In these occupations, the work performed and the training required are much the same in hotels as in other fields, and hotel employees make up only a small proportion of all employed workers. The employment opportunities for these occupational groups are affected by general conditions in their trades. The outlook for them in hotels is suggested by the trend of employment in this industry, which is described in the next section.

Young people interested in a career in hotel work usually have to begin at the bottom of the ladder—in jobs such as bellman, elevator operator, clerk, or maid. From these entry jobs, they may be promoted to supervisory positions, if they have the needed personality and ability. Exceptionally able and well-qualified men may advance eventually to managerial jobs, which are almost always filled by promoting workers with many years of hotel experience. Managers with sufficient capital and good experience have sometimes been able to go into business for themselves, as owner-operators of small hotels.

Trend of Employment

Employment in hotels will probably tend to increase slowly both in the next year or two and in the more distant future.

When the war ended, there were labor shortages in almost all hotel occupations. Wartime conditions brought a marked increase in hotel business, at the same time that large numbers of experienced workers were leaving to go into the armed forces or into higher-paid jobs in other industries. Though many inexperienced workers were hired and employment rose, the number of new recruits was not large enough to fill all the openings. With the return of former employees to the industry, the need for workers has been greatly reduced, but there still are openings in some occupations in many hotels. Additional opportunities will arise continually owing to turnover, which is especially high among the less skilled and lower-paid workers such as maids and kitchen help. Moreover, if the plans that have been made for building new hotels are carried out, these will create some further jobs within the next few years.

In the long run, a slow upward trend in employment in practically all hotel occupations is to be expected, as population and travel increase.

"HOTEL BUSINESS" - BY R. T. HUNTINGTON, 1940

Tourist camps and other lodging places will take some business away from hotels, as they were doing before the war, but the growing demand for lodgings should offset this competition in most localities as long as general business conditions continue to be good. Declines in business activity have led to sharp declines in hotel employment in the past, however, and would probably do so in the future; some occupational groups would be affected more than others. How stable employment is likely to be in different hotel occupations is one of the points discussed later on in this bulletin.

Earnings and Working Conditions

Earnings of hotel workers have risen greatly during the past few years, in line with the general upward trend in wages. Besides their money wages, nany workers are furnished meals and lodgings by he hotel. In addition, many receive tips from cus- omers. Not counting any of these items, the av- rage pay of employees in year-round hotels (ex- luding high-salaried executives and supervisors) vas 60 cents an hour in the first half of 1946. This as nearly twice as high as in 1940. Weekly wages n early 1946 averaged about $26 or $27 for approx- nately 44 hours' work.

The amount an individual hotel worker can ex- ect to earn depends, first of all on his occupation nd the degree of skill which it requires; also on ie size and location of the hotel, how well the orker does his job, and other factors. Large umbers of hotel employees, such as maids and isboys, are in unskilled occupations paying less an the average earnings cited. On the other nd, certain occupational groups make much more than the average, as is indicated by the earnings data for a few occupations given in later sections of the bulletin.

One of the advantages of work in year-round hotels is the fact that employment and earnings are likely to be steady throughout the year. Some employees of resort hotels, who move each fall from a hotel in the North to one in the South which is under the same management and then back again in the spring, also have steady jobs. More often, however, workers in this branch of the industry face the problem of finding new jobs when their hotel closes at the end of the season.

Hours of work and other working conditions vary greatly from one hotel to another and also from occupation to occupation. Although some workers, especially in large hotels, are on regular 8-hour shifts, many others have a longer workday. "Split shifts"—on which employees have several hours off duty during the day but start their work early in the morning and end it after dinnertime in the evening—are frequent among kitchen and dining-room workers. Owing to the fact that hotels provide service 24 hours a day, some employees must work at night; in some hotels, employees take turns at the different shifts.

In general, hotel work involves no serious accident hazards, nor are there any special industrial-disease hazards. In many occupations, however, workers have to be on their feet all day long and this may lead to various health problems.

Employees such as housekeepers and maids, who often "live in" and are provided with meals find that living conditions vary greatly from one hotel to another.

Employment Prospects in Typical Hotel Occupations

Front-Office Clerks

Everyone who has been in a hotel lobby has seen "front-office clerks" at work behind the main el desk. Their major responsibility is to rent ms to incoming guests, trying to give each one kind of room he wants for the length of time wants it. This is not always easy: guests want- double rooms with southern exposure do not always show up in exactly the numbers calculated by the architect who designed the hotel; and sometimes after room 703 is rented, Mr. Jones, who always stays in that room, arrives in the lobby with his baggage. Bearing in mind arrivals and departures from all the rooms in the hotel and trying to please all the guests, the clerks must try to make room assignments in such a way as to obtain the greatest possible room revenue. They also have many other duties, such as acknowledging room reservations received by telephone or mail and filing reservation cards; handling guests' complaints; issuing and receiving room keys; supplying information about arrivals and departures of guests and about local points of interest; receiving and delivering messages; and taking care of incoming mail.

In small hotels with few employees, one clerk may do all this work by himself or with the help of one or two assistants. Where there is a large staff, however, employees usually specialize in different types of work. In such cases, beginners are assigned routine jobs such as those of key clerk, information clerk, or mail clerk, and there are also higher-grade clerks with such titles as room clerk, desk clerk, or front-office manager, who supervise other clerical workers in addition to handling the more difficult and responsible work.

Openings in beginning jobs are filled sometimes by hiring inexperienced outsiders, sometimes by promoting bellmen, switchboard operators, and other workers already employed by the hotel. Positions of higher grade are usually filled by promotions from within but, in some instances, by hiring experienced clerks from other hotels. A supervisory clerk may be promoted to assistant manager, and, after becoming familiar with the operation of other departments of the hotel, may possibly become general manager. Men are generally preferred for front-office clerical jobs. High-school education is often helpful in entering and advancing in this work. Completion of a course in hotel work in the public schools, where one is offered, is also likely to be an aid in getting a job.

Room clerk filling out "rooming slip" showing guest's name and address and the room number and rate, while guest registers.

There will be some job opportunities in the immediate future, not only for experienced workers but also for newcomers who have the desired personal qualifications. During the war, about half of the many thousands of men employed in these occupations left for the armed forces and war industries. Although a large number of new clerks were hired, including many women, there was a shortage of help in both supervisory and lower-grade jobs. Some former workers have returned to their jobs since the end of the war, but the shortage has not been filled in all hotels. In addition, many hotels have been anxious to replace some of the clerks hired during the war. The best chance of jobs for inexperienced workers will generally be found in the larger commercial hotels, where beginners can be assigned o specialized jobs.

Because of the long-run upward trend and also ecause employment of front-office workers is only lightly affected by declines in general business ctivity, most men who find positions in year-round otels and prove satisfactory may expect to keep heir jobs for many years.

No up-to-date statistics on earnings in different otel occupations are available. However, scatred information for a few large cities suggests iat typical weekly salaries in beginning frontfice jobs were roughly $25 to $35 in the early part f 1946; in higher-grade jobs, about $35 to $45. arnings of head clerks tend to be somewhat gher, especially in large hotels.

Service Employees

The first worker one meets when coming into a tel is a member of the service department—the orman. Bellmen are a still better-known group service employees. Other workers in this dertment include elevator operators and starters, l captains, head baggage porters, and the superendent of service. These positions form a protional ladder up which men may move as they n in experience and skill. The usual steps in motion are outlined in the next three sections ribing the most important service occupations.

Bellmen and Baggage Porters

he ringing of a bell or the call of "Front!" in otel lobby quickly brings the "bellman" to r a guest up to his room and carry his baggage. Bellmen also run errands, deliver messages and packages, and supply various types of information to guests. In large hotels, a separate group of employees, known as "baggage porters," handle the suitcases and other baggage of guests who are leaving. They also help to set up sample rooms for salesmen, supply travel information and buy transportation tickets, and arrange for shipment of express articles. The duties of bellmen are frequently combined with those of baggage porters, except in large hotels, and the worker in such cases is generally known as a bellman. In some instances, bellmen and baggage porters act as relief men in such jobs as elevator operator and switchboard operator.

The way of entering these occupations differs from one hotel to another. Some hotels fill openings only by promoting workers already employed by the hotel—most often elevator operators and starters. Some also hire workers with experience in other hotels—as bellman or baggage porter or, occasionally, in another occupation. A good many hotels, especially the smaller ones, sometimes hire outsiders without previous hotel experience. In a few localities, training courses for bellman jobs are given by the public schools; completion of such a course is generally helpful in obtaining work.

A man who wishes to advance from the job of bellman may aspire to be bell captain. A baggage porter may advance to head baggage porter. From either position, the second step up is to become superintendent of service. Some workers have a chance to transfer to front-office clerical jobs, which may enable them to advance eventually to managerial positions. Moreover, both bellmen and baggage porters may increase their earnings by moving to jobs of the same kind in better-grade hotels.

These occupations are overcrowded, taking the country as a whole, although there are a limited number of openings in a few localities. As former workers have returned from the armed forces and war industries, many of the men hired during the war have been down-graded, usually to elevator-operator jobs, or have been laid off. Hiring standards have become much more strict.

During the next few years inexperienced men are likely to find it difficult to get positions as bellmen or baggage porters. In general, competition for jobs will be keenest in large commercial hotels in metropolitan centers. The chance of entering the occupations will probably be best in resort hotels, and experience gained there may enable men to transfer to commercial or residential hotels. It may also be possible for beginners to find jobs in occupations such as elevator operator or houseman in which there are still shortages of workers in some areas. These jobs may lead to positions as bellmen or baggage porters in the future. The length of time it will take to be promoted will vary greatly, however, depending upon the rate of turnover in the particular hotel and the number of employees with greater seniority.

Though the long-run trend is upward, employment in these occupations is very much affected by declines in business activity. Whether all bellmen and baggage porters will have steady employment over a long period of time will therefore depend on whether or not general business activity continues at a high level.

A fairly large number of bellmen and baggage porters belong to unions. The union members are mostly in large cities outside the South. They are represented by the Hotel and Restaurant Employees' and Bartenders' International Union, AFL, and in a few places by the Building Service Employees' International Union, AFL.

Wages in union hotels were about $12 to $16 per week in early 1946, according to scattered data for some large cities. Including tips, the total amount received by many bellmen was reported to be roughly $45 to $60 a week.

Bell Captains and Head Baggage Porters

The work of bellmen and baggage porters is generally done under the watchful eyes of the "bell captain" and the "head baggage porter." These supervisory employees are to be found in almost all medium-sized and large hotels, though seldom in small hotels with only a few service employees. It is their job to assign work in rotation to employees in their respective departments and to keep time records. They also instruct new employees, interview job applicants, investigate and adjust guests' complaints relating to the work of their departments, and decide what action should be taken on unusual requests for service. The head baggage porter is sometimes called a "transportation clerk" because of his expert knowledge of train and airplane schedules. The bell captain, in addition to his other duties, may occasionally perform bellman's work.

Bell-captain positions are usually filled by promoting one of the bellmen employed by the hotel; head-baggage-porter jobs, by promoting one of the porters. Although a man may advance to the job of superintendent of service from either position, bell captains are more likely to receive this promotion than head baggage porters.

Both occupations are small ones, employing only a few thousand workers. In both, the number of men employed declined slightly during the war. Vacancies created by withdrawals to the armed forces and war industries could not always be filled and, often, part or all of the duties were taken over by other employees such as the superintendent of service, room clerk, or assistant manager. The shortage of qualified workers has largely been met, however, by the return of most of the men who left; only a small number of

Bell captain receiving telephone request for service from a guest, while a bellman waits for instructions.

openings remain. These openings, plus those arising because of turn-over, will, as usual, be filled in most instances by promoting the most qualified bellmen and baggage porters. Men who obtain such promotions in year-round hotels will have a good chance of holding their positions indefinitely, since employment in these occupations is not affected very much by declines in general business activity and will probably tend to rise slowly over the long run.

Typical weekly wages of both bell captains and head baggage porters were roughly $35 to $45 in the early part of 1946, according to fragmentary data for a few large cities. Total earnings were higher, however, because of tips. The amount of money earned through tips varies considerably from one hotel to another. In general, head baggage porters make more than bell captains, because they receive larger and more frequent tips—mainly for making travel arrangements and pur- hasing tickets.

Superintendents of Service

At the head of the service department in some rge hotels is the "superintendent of service." He ires, instructs, disciplines, and discharges em- loyees in his department. In addition, he confers nd cooperates with the people in charge of other partments—for example, the chief clerk and the usekeeper—and he may also make out the pay ll for his department. In smaller hotels, these ties are performed, as a rule, by the assistant or neral manager, the room clerk, or the bell cap- n (who may be called "working superintendent service").

Ten years of hotel experience is often necessary order to become a superintendent of service. As eady indicated, most employees in this occupa- n have been promoted from the job of bell cap- n, though some were previously head baggage ters. Occasionally, a superintendent of service nsfers to a front-office clerical job, with the aim advancing eventually to a managerial job.

mployment is likely to rise slightly above the sent figure, which is in the hundreds, during the t few years. During the war, a small number nen left the occupation for the armed forces war industries. As in the case of bell captains head baggage porters, vacancies were not al- s filled and employment therefore declined somewhat. With the return of most of the men who left, employment has risen again, and the occupation has become overcrowded in most parts of the country. A few openings may be expected as a result of turn-over and the long-run upward trend in hotel employment but these will, as usual, be filled by promotions from within. Since this is another occupation that is little affected by declines in general business activity, the small group of men who succeed in obtaining positions in year-round hotels should have steady employment for many years.

On the basis of scattered data for some large cities, it appears that typical wages were approximately $40 to $60 a week in this occupation in the early part of 1946. A few men who work in very large hotels earn more. Tips are seldom received, but meals may be provided by the hotel. The number of hours of work per day and per week vary greatly, depending upon pressure of work.

Housekeepers and Assistants

The furnishings, rooms, and halls of hotels must be kept clean and attractive—and this is the housekeeper's responsibility. The housekeeper supervises the work of room maids, linen maids, wall and window washers, furniture polishers, housemen (who do heavy cleaning), and seamstresses. Generally, she hires and discharges employees in her department. In addition, she buys or assists in the buying of supplies, reports expenditures to the manager, makes out the pay roll for the department, takes periodic inventories of supplies, and trains new employees.

Large hotels have an executive or head housekeeper and also one or more assistant housekeepers and floor housekeepers or inspectresses. In small hotels, on the other hand, there is only one housekeeper (often called a "working" housekeeper) who not only handles all the supervisory duties by herself but may, in addition, do some of the work of a maid.

Openings for housekeepers are usually filled by promotions from within the hotel or by hiring women who have performed similar work in another hotel. Positions as inspectresses or assistant housekeepers in large hotels are filled sometimes by hiring inexperienced women and giving them on-the-job training; sometimes by promoting chambermaids, linen maids, and seamstresses.

From these assistant supervisory jobs, promotion to the position of housekeeper is possible. Training courses for housekeeping jobs are given by the public schools in some localities and are likely to be helpful to girls wishing to enter the occupation.

Many thousands of housekeepers and assistants are employed in the industry as a whole, and their number is likely to increase slowly both during the next few years and in the long run. The shortage of workers which developed in those occupations during the war has been much reduced since VJ-day, but there are still some vacancies, especially in small hotels and in lower-grade jobs. In addition, there will be hundreds of openings a year owing to turn-over. As already indicated, however, inexperienced women will be able to find jobs only as maids or, if they have the desired personal qualifications, as assistant housekeepers or inspectresses. Moreover, competition for the better-paying jobs in large hotels is likely to be keen, as it was before the war.

Housekeeper supervising a houseman in hanging drapes and inspecting the color of paint before it is put on the walls.

The long-run trend of employment in this occupation is upward also. Women who obtain promotions to housekeeper jobs in year-round hotels should have a good chance of holding them indefinitely. Assistant housekeepers and inspectresses, however, have less assurance of steady employment, since declines in general business activity affect the number of assistants needed to a much greater extent than the number of top jobs. Th number of maids employed is likely to be still mor affected by changing business conditions.

Earnings of housekeepers, according to limite data for a few large cities, were about $150 to $35 a month in large hotels and $75 to $100 in smal hotels in early 1946. In addition, housekeeper are often given their meals and, sometimes, room as well. Assistant housekeepers and inspectresse make less.

Managers and Assistants

Over-all responsibility for the operation of a hotel rests with the manager. It is his job to see that the different departments function efficiently, so that the guests are satisfied and the greatest possible profit is made. The manager has many luties to perform, such as hiring personnel, buyng or supervising the buying of supplies, directng publicity, introducing improvements in service, nd determining rates and credit policies. In arge hotels, some of these duties are delegated to ssistant managers. In small hotels, on the other and, the manager—who is frequently the owner—ay also do front-office clerical work.

Advancement to the position of manager is ossible from many hotel jobs, including bellman, okkeeper, and cook, but the most common line promotion is from the front office. To qualify r promotion to manager, it is often necessary to ve a high-school education and very helpful to ve college training, especially in hotel manageent. College-trained persons often start in such sitions as room clerk, auditor, sales manager, countant, purchasing agent, or, sometimes, astant manager.

Each of the 28,000 hotels in the country has a nager, and big hotels also have one or more istant managers. At the present time, these upations are overcrowded. As former workers e returned to their jobs from the armed forces and war industries since VJ-day, some of the men who were placed in managerial positions during the war have been downgraded or laid off. Men without experience in such positions will therefore find it very difficult to enter the occupations in the immediate future.

In the next few years and also in the long run, employment will tend to rise slowly as new hotels are built. In addition, there will be hundreds of job openings a year, owing to deaths, retirements, and transfers to other fields. As in the case of managerial positions in many other fields, however, competition for jobs is keen. Therefore, only men with exceptional ability and many years of experience will be able to obtain positions as managers, especially in large hotels. In general, the trend is toward filling openings by promoting college-trained persons with hotel experience, but it will still be possible for some men without such education to rise very slowly to the top jobs.

Most managers and assistant managers may look forward to continued employment over a long period of time, both because of the long-run upward trend in hotel employment and because, in this occupation also, employment is little affected by declines in general business activity.

Earnings of managers have an extremely wide range and largely depend upon the size of the hotel. In addition to a fixed salary, many managers receive a percentage of the profits and frequently living accommodations and meals for themselves and their families.

How To Get More Information About Job Opportunities

The descriptions of job opportunities in typical hotel occupations refer to conditions in the country generally. Individual hotels and local areas may for various reasons offer better or poorer chances of employment. Information on opportunities and how best to obtain a job in a particular locality, in the occupations discussed in this bulletin or in other hotel work, may be obtained in several ways. The applicant may go to any local office of his State employment service, affiliated with the U. S. Employment Service. He may obtain the addresses of nearby hotels from the classified section of the telephone book and go directly to these establishments. If he lives in a city where there is a local office of the American Hotel Association, or locals of the Hotel and Restaurant Employees' and Bartenders' International Union, AFL, or of the Building Service Employees' International Union, AFL, he can obtain helpful information by writing or visiting these organizations. Information may be obtained also by writing to their national offices at the following addresses:

American Hotel Association, 221 West 57th Street,
New York 19, New York.
Hotel and Restaurant Employees' and Bartenders'
International Union, AFL, 528–530 Walnut
Street, Cincinnati 2, Ohio.
Building Service Employees' International Union,
AFL, 130 North Walls Street, Chicago 6, Illinois.

One of the best ways to get information on training courses in hotel work is to write to the State Director of Vocational Education at the Department of Education in the State capitol.

Occupational Outlook Publications of the Bureau of Labor Statistics

Studies of employment trends and opportunities in the various occupations and professions are made by the Occupational Outlook Service of the Bureau of Labor Statistics.

Reports are prepared for use in the vocational guidance of veterans, young people in schools, and others considering the choice of an occupation. Schools concerned with vocational training and employers and trade-unions interested in on-the-job training have also found the reports helpful in planning programs in line with prospective employment opportunities.

Occupational Outlook reports are issued as bulletins of the Bureau of Labor Statistics; sometimes they are also published in the Monthly Labor Review (subscription price per year $3.50; single copy, 30 cents). Both the Monthly Labor Review and the bulletins may be purchased from the Superintendent of Documents, Washington 25, D. C.

Two types of reports are issued:

Occupational Outlook Bulletins describe the long-run outlook for employment in each occupation and give information on earnings, working conditions and, the training required.

Special Bulletins are issued from time to time on such subjects as the general employment outlook, trends in the various States, and occupational mobility.

Occupational Outlook Bulletins

GUARANTEED WAGE OR EMPLOYMENT PLANS

Bulletin No. 906

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

GUARANTEED WAGE OR EMPLOYMENT PLANS

Bulletin No. 906

A reprint of Appendix C from Guaranteed Wages: Report to the President
by the Advisory Board, Murray W. Latimer, Research Director

LETTER OF TRANSMITTAL

United States Department of Labor,
Bureau of Labor Statistics,
Washington, June 9, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report on guaranteed wage and employment plans, which was prepared in the Bureau's Wage Analysis Branch and submitted to the Office of War Mobilization and Reconversion for inclusion in their final report. The field work was conducted under the direction of the Bureau's regional wage analysts.

Ewan Clague, *Commissioner*,

Hon. L. B. Schwellenbach,
Secretary of Labor.

PREFACE

In the summer of 1944 the Bureau of Labor Statistics began an inquiry into the subject of guaranteed wage and employment plans, anticipating a general demand for information on the nature of such plans and of the Nation's experience with them. At the time the Bureau began its inquiry, union demand for a guaranteed annual wage was at issue in a dispute case before the National War Labor Board, involving the basic steel industry and the United Steel Workers of America. In rendering its decision in November 1944, the Board refused to grant the union's demand under conditions prevailing at the time. However, in view of the lack of adequate information relating to guaranteed annual wage plans, it was recommended that a thorough study of the subject be made by a special commission to be appointed by the President.

On March 20, 1945, the President designated the Advisory Committee of the Office of War Mobilization and Reconversion to survey "the whole question of guaranteed wage plans and the possibility of their future development in American industries as an aid in the stabilization of employment and the regularization of production." Following this action, the Bureau's program was carried on in cooperation with the Guaranteed Wage Study Staff, designated by the Office of War Mobilization and Reconversion to investigate the problem. In December 1945, the Office of War Mobilization and Reconversion submitted to the Bureau of Labor Statistics a request for a survey of specific experiences with existing and discontinued guaranteed wage and employment plans.

The following report summarizes the major findings of the Bureau's survey, and appears as Appendix C of the Final Report to the Advisory Board of the Office of War Mobilization and Reconversion which was prepared by the Guaranteed Wage Study Staff.

The Bureau's forthcoming final report on guaranteed wage and employment plans will include an analysis of the major characteristics of a number of individual plans.

APPENDIX C—GUARANTEED WAGE OR EMPLOYMENT PLANS

DEFINITION AND METHODOLOGY EMPLOYED IN THIS STUDY

DEFINITION

The Bureau of Labor Statistics has included in its study of guaranteed wage or employment plans all arrangements, written or unwritten, by which an employer guaranteed or assured to some or all of his employees, in advance, a definite period of employment equal to at least 3 months a year, or an equivalent amount of wages.

This definition is broad, and covered plans framed in a variety of ways: plans which were lesignated as "guarantees" by the employers and mions which operated under them, and plans vhich did not carry the title of "guarantee" but vhich in fact operated as guarantees. In a rela- ively small number of cases, the plans provided or an "annual wage." In the majority of cases, mployment was guaranteed for a stated number of eeks per year and hours per week, frequently ss than 52 weeks per year and 40 hours per week. n practice, these guarantees of employment, as ell as the few guarantees that were explicitly ated in terms of wages, did guarantee wages for e total number of hours a year over which em- oyment was guaranteed. A distinction between uaranteed wage" and "guaranteed employment" ans was unnecessary for the purpose of this dy.

Despite the general inclusiveness of the defini- n employed, a number of problems arose re- ecting its application in border-line situations. e distinction between a guarantee plan and a vate unemployment benefit plan, for example, s difficult to draw. The latter were included y where the period of time over which benefits re paid was 3 months or more and where there s a commitment to pay benefits regardless of size of reserves set aside for this purpose.

t was difficult also, in many instances, to draw line between a guarantee and an employer's oral pledge that work in his establishment would be "steady." A large degree of stability is inherent in many types of industry. Moreover, many employers have maintained fairly stable employment in their plants, frequently as a result of planned production and hence employment regularization, without instituting formal guarantees. The volume of employment regularization planning in this country is, in fact, far greater than that encompassed by the actions of the firms that have guaranteed wages or employment. The practice of employing white-collar personnel on an annual rate basis is widespread, especially in government, financial, and institutional establishments. Guarantees of minimum weekly hours or wages are found in many labor agreements, notably in the meat-packing and trucking industries; the practical effect of these arrangements is to afford a guarantee of almost full weekly earnings even when wage earners work only during some part of each week. In none of these situations, however, is there a formal pledge or assurance of continued employment, and the employee is not free from the possibility of lay-off or loss of his job. Oral arrangements (amounting to 36 percent of the currently operating plans included in the study) were included only where there was a formal guarantee or assurance of continued employment or wages.

Many of the plans contained the theoretical possibility of abrogation or modification during the life of the guarantee period under various circumstances. Provisions for modification or cancelation of an announced guarantee did not result in exclusion of the plan from the study.

The so-called wage advance plan was another type of guarantee which raised questions of inclusion. Such plans are sometimes regarded as loan arrangements, because their central feature is the advancement of wages by the employer during short-hour weeks, and the repayment by workers during weeks in which longer hours are worked. They are different from loan plans in essential characteristics, however. Where there was no obligation to repay the advance unless the employer provided sufficient work to enable the advance to be repaid, the plan was considered to be a guarantee of wages or employment for the maximum period over which wages were advanced, and was included in the study.

METHODOLOGY

On March 1, 1945, the Bureau of Labor Statistics mailed a brief questionnaire to about 90,000 employers for the purpose of determining the extent to which guarantee plans had been adopted in the United States. From the replies to this questionnaire, from a canvass of previous studies and available literature on the subject, and from a list of employers who had filed contracts with the Wage and Hour and Public Contracts Divisions under section 7 (b) (2) of the Fair Labor Standards Act, the Bureau was able to compile a list of firms which appeared to have had a guaranteed wage or employment plan in effect at some time. The Bureau then conducted a field inquiry to determine finally whether these arrangements actually met the requirements of the definition of guaranteed wage or employment plans used in this study, and whether these plans had actually operated. At the same time, information was collected on the basic features and provisions of those plans which met the definition that had been established. A total of 241 plans (196 still in operation and 45 that had been discontinued) were surveyed in this manner and are included in the tabulations in this report. To this group were later added 106 additional discontinued plans about which information was obtained subsequent to the field survey. This number included 96 cases which operated under the Wisconsin unemployment compensation law in 1934 and 1935.

In addition, the Bureau made more specific and detailed investigations of the operations of 62 of the plans and the situations into which they were introduced. Some of the material gathered in the course of this subsequent investigation is also presented in this report.

HISTORICAL DEVELOPMENT OF PLANS[1]

INITIATION OF PLANS

Until the passage of unemployment compensation legislation, the history of guarantee plans was part of the history of individual efforts, unaided by government, to mitigate the effects of unemployment in particular industries and plants. During this early period, the idea of guaranteeing wages was not differentiated from other unemployment compensation arrangements. In fact, the term "guaranteed wages" was not used in connection with early plans that have since come to be known as "guaranteed wage" or "guaranteed employment" plans. A good example of this situation was reflected in the language of the Procter & Gamble Co. plan, introduced in 1923, which provided a 48-week-a-year guarantee of employment by assuring that no worker would be unemployed for more than 4 weeks a year.

Trade union sponsorship and individual employer initiation were both important in the early history of guarantees. During the nineteenth century trade union activity had in several instances encompassed the furnishing of out-of-work benefits to members, but such arrangements, of course, carried no obligations by employers to furnish work. The first plans in which employers assumed responsibility for providing work or wages were those of the decade of the 1890's, negotiated in the wallpaper industry, by brewery workers, by textile printers in a New Jersey dyeing and finishing establishment, and established by a small midwestern retailer of sporting goods.

Best-known among the early guarantee plans were those in the wallpaper industry. A guarantee of 11 months' employment was first introduced in 1894, as a result of negotiations between the National Association of Machine Printers and Color Mixers and the National Wall Paper Company, then a newly formed amalgamation controlling from 50 to 75 percent of the industry. In 1896 the guarantee was extended to 12 months a year; modifications were made in subsequent years. The independent companies in the industry followed the bargaining pattern set by the largest firm, and the plan became industry-wide for members of the wallpaper association who bargained with the union. Similar arrangements were made by negotiation with the National Print Cutters' Association of America, which in 1923 joined with the National Association of Machine Printers and Color Mixers to form the United Wall Paper Crafts.

---

[1] The material in this section of the report is based upon data gathered by the Bureau of Labor Statistics and upon published accounts of guaranteed wage or employment plans.

Among the other early arrangements, that involving the National Union of the United Brewery Workmen of the United States is known to have arisen in at least two areas, Philadelphia and New York, and took the form of contract provisions restricting lay-off of regular employees to no more than specified numbers of days during the dull season of the year. The agreement between the Machine Printers Beneficial Association and a New Jersey textile finisher provided each journeyman printer full pay for any period of unemployment prior to July 15 of each year, and half pay for any period of unemployment during the remainder of the year. The plan of the midwestern sporting goods retailer provided an oral guarantee of 52 weeks' pay each year to all employees who had passed a probationary period of approximately 90 days.

Guarantee plans introduced during the early years of the twentieth century involved small establishments in which employers made oral commitments to all or some of their workers to provide them with year-round employment. A retail men's furnishing store, starting in 1905, guaranteed permanent employees 52 weeks of work at full veekly hours; a coffee-roasting establishment, in 1912, began to pay its production workers full veekly pay during slack season weeks; a poultry-leaning establishment began, in the following ear, to guarantee 52 weeks of full-time employ- nent to permanent workers; a small department tore began the same guarantee in 1914; and a nall drug firm about 30 years ago instituted year-round weekly wage payment plan covering employees.

The next well-known plan, that of the Columbia onserve Company of Indianapolis, a producer soups and other canned products, appeared in 17. The guarantee was part of a broader social periment which included profit-sharing and an nployee council to give permanent workers a voice in the management of the enterprise. Phases of the experiment which attracted public attention included the steps taken by the company after introduction of the plan to level out its normally seasonal production pattern, and the eventual turning-over of ownership to the permanent workers covered by the guarantee.

Employer interest in the problem of employment security is reported to have increased substantially after the business depressions of 1914 and 1921, and also as a result of the increasing general interest in scientific management and improved personnel procedures. A number of unemployment benefit plans, many of which had characteristics that are currently attributed to guarantee plans, were adopted during the period between 1919 and the passage of Federal and State unemployment compensation legislation. These plans typically provided for the payment of out-of-work benefits rather than for a guarantee of continuous employment. Where the unemployment benefits covered an extended period of time, the line of demarcation between an unemployment benefit plan and a guarantee plan was difficult to distinguish. As has already been indicated, unemployment benefit plans that provided assurance of benefits for 3 months or more have been included in the data on guaranteed wage or employment plans presented later on in this report.

Several unemployment benefit plans are worthy of mention at this point because of their similarity to many of the early guaranteed wage or employment plans. None of them were included in the data contained in subsequent sections of this report, because they did not meet the 3-month guarantee test referred to above. In 1919 the Dutchess Bleachery, followed in 1920 by an affiliate, the Rockland Finishing Co., began setting aside part of its profits in order to provide its workers half pay during periods of unemployment. The American Cast Iron Pipe Co. introduced an unemployment benefit plan in 1924; the Brown & Bailey Co. did likewise in 1927. During the same period of time, a number of unemployment benefit plans were introduced by joint agreement between management and labor, notably in the needle trades in New York and Chicago, and in the hat and lace industries.

Among the plans introduced during the 1920's that can be classed as guarantees, the most notable were the joint agreements of the Cleveland garment industry and the International Ladies' Garment Workers Union (1921), the plan of Crocker-McElwain Co. and its affiliate, the Chemical Paper Co. (1921), the Procter & Gamble Co. plan (1923), and the joint agreement between the Seaboard Airline Railway and a federation covering its shop craft employees (1928). The plan in the Cleveland ladies' garment industry was the first of several unemployment compensation devices introduced in the apparel industry during the 1920's, and the only one that qualified as a guarantee under the definition used in this study. By agreement with the International Ladies' Garment Workers Union, Cleveland apparel manufacturers guaranteed 20 weeks of full employment in each 6-month period (later changed to 40 weeks a year), at two-thirds of minimum weekly wages (later changed to half of minimum wages). The Crocker-McElwain plan assured year-round employment at full pay to workers with at least 5 years' service; in subsequent years this plan was modified to provide, finally, less than 50 percent of full-time annual compensation. The Procter & Gamble plan assured 48 weeks' employment to all workers with at least 6 months' service. Since the time of its introduction, the plan has been somewhat modified, principally by limiting eligibility to workers with at least 2 years' service. The Seaboard plan as originally introduced was a guarantee of annual employment for an agreed-upon number of shop employees each year.

As was the case during the earlier two decades of the century, the occasional introduction of a less formal plan by small employers continued. A shoe retailer guaranteed and maintained year-round employment to 15 regular employees starting in 1923; a commercial machinery wholesaler guaranteed 52 full weeks' pay a year to 2 service mechanics; beginning about 1924, a Michigan coal dealer guaranteed weekly wages throughout the year to 7 employees regardless of prevailing conditions; in the same year, a garment manufacturer introduced a guarantee of 52 weeks' full pay covering a group of key workers; from 1 to 4 plans of similar character were introduced during each of the remaining years of the 1920's.

Introduction of guarantees and unemployment benefit plans continued during the depression of the early 1930's. The General Electric Company in 1930 adopted an unemployment-pension plan, covering 12 of its electrical apparatus manufacturing plants, and in 1931 adopted a plan guaranteeing 50 weeks' work of not less than 30 hours each (modified in subsequent years) to employees with 2 years or more service in 12 lamp manufacturing plants. The Wm. Wrigley, Jr. Co. in 1934 adopted an employment assurance plan with unemployment benefits varying according to a sliding scale dependent on pay level and length of service. The plan of Geo. A. Hormel & Co., meatpackers of Austin, Minn., was started on a small scale in 1931 and its scope gradually extended until in 1940 it covered all but a small percentage of the company's employees.

During and following the depression of the early 1930's, the character of the plans introduced shifted from guarantees of unemployment benefits to guarantees of continued employment. Compulsory unemployment insurance legislation was adopted in Wisconsin in 1932 and at later dates in other States, the latter chiefly under the provisions of the Federal Social Security Act. The legislation permitted modification of the contribution or tax features in the cases of employers who provided guarantees of employment or wages equivalent to legislatively-established standards. The chief, and as far as can be ascertained, the only direct effect of the legislation upon the introduction of guarantee plans occurred in the case of the Wisconsin law, which completely exempte from the unemployment tax employers who guar anteed 42 weeks' pay (at 36 hours a week, change in 1935 to 40 weeks at two-thirds of full-time) t their workers. A total of 96 employers operate guarantee plans under this law for a period c slightly more than a year, beginning in 1934 an ceasing at the end of 1935. At that time the sta utory provisions in Wisconsin were changed conform to the requirements of the Federal sta ute, applicable to all State unemployment co pensation laws, under which employers who gua anteed employment or wages were given t credits, but not complete exemption. Only additional States—California, Florida, Ida Indiana, Minnesota, and Oregon—are reported have made provision in their unemployment co pensation laws for guarantee plans, but none them implemented the clauses with the necess administrative regulations. No guarantee plans were ever adopted under these laws.

Further legislative provision affecting guarantee plans was made in 1938, when the Fair Labor Standards Act was adopted. Under section 7 (b) (2) of this act, exemption from penalty overtime provisions (up to 12 hours a day or 56 a week) was granted in cases where workers were employed—

> "on an annual basis in pursuance of an agreement with his employer, made as a result of collective bargaining by representatives of employees certified as bona fide by the National Labor Relations Board, which provides that the employee shall not be employed more than 2,080 hours during any period of 52 consecutive weeks."

To date, very few employers have used this exemption. The most substantial plan operating under the provision is that of Geo. A. Hormel & Co., which had been in operation prior to the passage of the act.

During the period following the depression of the early 1930's, greater numbers of plans were introduced yearly than in any year prior to the depression. During the years 1938–42 new plans were introduced at the rate of from 19 to 23 a year, compared with a maximum of 4 a year during the 1920's, and from 2 to 6 during the early 1930's. The latter half of the 1930's saw the introduction of a number of "basic crew" provisions in agreements in the wholesale and retail trades. Under hese contracts, specified numbers of workers, ranging from less than half to well over three-quarters of the workforce, were guaranteed full weekly wages throughout the year.

The last of the well-known plans, that of the Nunn-Bush Co., was established in 1935. This lan early in 1946 guaranteed a continuous em- loyment relation to workers with the greatest seniority, and provided that the total earnings f all workers with 2 years' service (including, ut generally exceeding, the number of workers ho had the employment relation guarantee) hould be a predetermined proportion, no less han 20 percent of the wholesale value of the ompany's product. Workers shared in this mount in proportions determined by rates which flected job differences.

By the beginning of 1946, according to the in- rmation which has been compiled by the Bu- eau, a total of 347 plans which met the definition ed in this study had been introduced. A year-by-year tabulation of the time of their initiation is shown in table 1.

DISCONTINUANCE OF PLANS

Of the plans known to the Bureau of Labor Statistics that had been introduced up to the beginning of 1946, 196 were still in existence at that time. The remainder, a group including all of the 96 plans introduced in 1934 under the Wisconsin unemployment compensation law and 55 others, had been discontinued before the end of 1945.

In the case of the 96 Wisconsin plans and a small number of others, discontinuance resulted from the circumstances surrounding the introduction of compulsory unemployment insurance legislation. In the case of the Wisconsin plans, amendment of the State law to conform with the requirements of the Federal Social Security Act removed the tax exemption which the companies had enjoyed under the former statute, and the employers thereafter individually elected not to come under the guaranteed account provisions of the legislation. In a few other cases, plans that had been instituted prior to the passage of compulsory unemployment compensation legislation were discontinued upon the passage of such laws because it was believed that the objective which the plans were designed to meet was met by those laws.

In the remainder of the cases, discontinuance was largely the result of special individual circumstance, in a number of cases related to the general state of business conditions at the time the plans were discontinued, but on the whole the result of problems facing the individual employer.

Two of the earliest plans abandoned were those of the American Cast Iron Pipe Co., discontinued in 1926, and the Consolidated Water Power & Paper Co., discontinued in 1929. Only incomplete information is available on the reasons for their discontinuance: The former was discontinued on the eve of a major technological change in the industry, the latter during a period of relatively full employment. The wallpaper plan—one of the earliest begun—was discontinued in 1930, after a considerable amount of dispute over the plan's administration, and in a period when depression conditions and the rise of substitute materials were seriously affecting the industry.

The plan of the United Diamond Works, under which benefits had been paid for almost a full year during the 1921–22 depression, ended in 1931, following a period of uncertainty in the industry to which international tariff problems contributed. In the same year the unemployment benefit plans of the Brown & Bailey Co. and the Cleveland garment manufacturers were discontinued; in the latter case the reason is reported to have been the long-range decline of the local market and the shift in the character of the industry. The plans of the Leeds & Northrup Co. and the Dennison Manufacturing Co. were discontinued in 1932 when their unemployment benefit reserves were exhausted. The depression years also saw the disappearance of many of the unemployment benefit plans not included in this study (those that could not meet the test of a 3-month guarantee), resulting chiefly from depletion of their individual unemployment compensation reserves.

Of the plans discontinued after the depression of the early 1930's, 15 were studied in detail by the Bureau, and information is available concerning the circumstances of their discontinuance. The effects of the depression seem to have been an important contributory cause of abandonment in only one case, where the guarantee was substantially modified to provide less than 50 percent of the earnings originally guaranteed, and the plan was finally abandoned in 1937. Four of the plans were abandoned during World War II, largely as a result of wartime business uncertainties. Four were abandoned after management had come to the conclusion that the plans were not needed, because the employer was able to provide substantially more work than the guarantee assured. All but one of these plans had been in existence for 3 years or less, and all were abandoned between the years 1939 and 1942. Three plans—two of which were introduced to avoid overtime compensation and one of which was introduced as an alternative to a wage increase—were abandoned as a result of employee dissatisfaction with the plan and union opposition. One of the remaining three plans was abandoned following the passage of unemployment compensation legislation; another was ended during World War II when management became worried about possible conflict between its obligations under the plan and its obligations to returning veterans, and when a newly organized unio showed indifference to the plan's continued existence. Finally, the plan of the Columbia Conserv Co., which had operated successfully over a perio of 25 years and through three periods of busines depression, was abandoned as the aftermath of labor dispute. Wages and union organization ha arisen as issues among the employee-owners, r sulting in a National War Labor Board dispu case and a court suit. The employee-ownersh feature of the plan was ended by court order as result of the suit, and the management of the co pany simultaneously ended the guarantee. In t s case, as in a number of other cases where pla s were discontinued, management and union rep sentatives expressed great interest in possible ture attempts at guaranteeing employment r wages.

As can be seen from table 2, guarantee pl s were discontinued from time to time during ne entire span of years over which plans have en in existence. With the exception of the year 1935, when the 96 Wisconsin plans were discontinued, there is no significant concentration. It is noticeable, too, that the discontinued group includes plans which had been in existence for varying lengths of time. Some, like the wallpaper plan and the plan of the Columbia Conserve Co., were among the oldest plans on record, while others had been in operation for only a few years when they were dropped.

THE NET STATUS OF PLANS

As has already been shown, the net result of the ntinued inauguration of new plans and the dis- ntinuance of others was a total of 196 during early part of 1946. With the exception of the r 1935, when the 96 plans adopted under the sconsin unemployment compensation law were continued, the picture, as shown in table 3, is one of constant growth of the number of plans in existence, at an accelerated rate during the period since 1934.

THE EXTENT AND NATURE OF GUARANTEED WAGE OR EMPLOYMENT PLANS IN THE UNITED STATES

CURRENTLY OPERATING PLANS

Prevalence

In January 1946, the 196 guaranteed wage or employment plans known by the Bureau of Labor Statistics to be in operation in the United States covered a total of approximately 61,000 workers. Some of the plans were master contract arrangements, involving a number of employers and unions in the same industry and community, and others were plans which covered several plants of the same company. As a consequence, the number of establishments was, of course, considerably greater than the number of plans. There were, in all probability, additional bona fide plans that were not included in the study. Compared with the total number of establishments or wage earners in the United States, the coverage of all guaranteed wage or employment plans is small. It is estimated to be less than 1 percent of the total number of wage earners employed in nonagricultural, nongovernmental establishments. The significance of the plans lies, however, in their provisions and accomplishments, rather than in their prevalence.

The 196 plans were found in a great many industries. Almost 40 percent of them, involving 38 percent of total employment covered, were in manufacturing industries. Within the manufacturing group, the plans were most frequently found in industries which have substantial seasonal variations, and those which produce for consumer demand. The greatest numbers of plans occurred in establishments manufacturing food products—brewing, meat packing, grain and flour; in textile mills—primarily in dyeing and finishing establishments; and in apparel companies. Relatively few plans were found in heavy or basic manufacturing industries, which are subject to much wider cyclical fluctuations, but often to less marked seasonal variation (table 5).

TABLE 5.—*Number of currently operating guaranteed wage or employment plans in the Bureau of Labor Statistics survey, by industry group*

Nonprofit membership organizations	1

Outside manufacturing industry, the greatest number of plans was in the retail trade group As in the case of the manufacturing industrie which produced consumer products, the establishments in retail trade were in many instance in lines of activity that were subject to significan seasonal variation: mail order houses, clothin stores, department stores. The same was true o establishments in wholesale trade, which contained the next most numerous group.

The detailed studies of experience with guaranteed wage or employment plans in 62 case demonstrated about as wide a variety of month to-month employment variations as exists in all American industry. Within individual industries or groups of plants, the studies did not point to the existence of special situations or exclusive processes that might have led to greater employment stability or served to give competitive advantage among the companies which had guarantees in effect. An overwhelming majority of the guarantees, in fact, were introduced by firms which faced employment stabilization problems of the same kind that are faced by employers generally.

The majority of the establishments that guarnteed employment or wages were located in the ndustrial regions of the country. More than 70 ercent of the 196 were in the Middle Atlantic nd Great Lakes regions, and almost 45 percent ere in the cities of New York, Chicago, Clevend, and Philadelphia. Very few were found n the Southeast, Southwest, or West. The folwing cities had the largest numbers of plans:

Chicago, Ill	10
Cleveland, Ohio	10
Detroit, Mich	6
Milwaukee, Wis	5
New York, N. Y	61
Philadelphia, Pa	5

Plans were found in establishments of all sizes. though most of them were in small establishents. Table 6 contains a distribution of the al number of wage earners in establishments ered by the plans in 172 cases for which such ormation was available. While in several cases employment data for individual plans group ether the employment of a number of establments, as in the cases of master contracts and panies with more than one establishment un- the same plan, the table gives a fairly good ture of the size of the establishments involved. ut 55 percent of the plans were in employing s of less than 50 persons; an additional 10 per- of the plans were in employing units of 50 00 persons. Ten percent of the plans were in loying units of 1,000 persons or more.

[1] A guaranteed wage or employment plan embodied in a master contract between a trade association and a union is counted as a single plan, and is classified according to the total number of wage earners in all of the covered establishments. There are 10 such cases.

[2] Includes 1 master contract plan.

[3] Includes 7 master contract plans.

In 130 of the 196 plans, unions represented the employees covered by the guarantees in general collective bargaining relations (table 7). Where one union was involved, the unions were A. F. of L. affiliates in 36 cases, C. I. O. affiliates in 64 cases, and were unaffiliated in 13 cases. In 17 cases there were 2 or more unions of different affiliation representing the workers. In a majority of the cases where unions represented the workers, the plans were subjects of collective bargaining. In a number of cases, however, the plans were introduced prior to unionization and have not since been included within the scope of collective bargaining.

Characteristics

The basic features of the guarantee plans may be characterized best in terms of the kinds of workers eligible for coverage and the requirements which workers must meet before they are eligible for benefits, the proportions of workers actually covered, and the amounts of wages or employment guaranteed.

In 101 of the 196 plans, as indicated in table 8, coverage under the plan was open to all or nearly all workers (in some cases to all production workers, and in others to some or all other wage earners as well, including office workers, supervisory force, salesmen, etc.). In 63 of these cases, employees automatically became eligible upon hiring or within 30 days thereafter. Service requirements ranged from 3 months to more than 5 years in all but 4 cases; in these the duration of the requirement was indefinite, depending upon the employer's judgment concerning the necessary probationary period. In a large number of cases, especially where there were union contracts, the eligibility period coincided with the probationary period provided in the contract for the attainment of permanent status or a place upon the seniority rolls.

Table 8.—*Eligibility requirements in currently operating guaranteed wage or employment plans in Bureau of Labor Statistics survey, by representation of covered workers*

Eligibility requirement	Number of currently operating plans		
	Total	Union	Non-union

Upon selection by employer	4	------	4
Coverage includes only employees in "regular" jobs	35	29	6
Coverage open only to employees in specific departments or occupations	51	45	6
Upon hiring or after service of 30 days or less	36	32	4
Upon service of 3 months or more	9	7	2
Upon selection by employer	2	2	------
Employees in "regular" jobs only	3	3	------
Unknown	1	1	------
Coverage confined to key employees	9	2	7

Coverage was open only to employees in "regular" jobs in 35 of the 196 plans. The limits of this kind of coverage were in some cases established by "basic crew" contract provisions that specified the numbers of workers who were to be covered, and in other cases were established by specific elimination of "temporary," "extra," or other similar groups of workers. Limitation of the guarantee to regular workers occurred chiefly in retail and wholesale establishments, and additional length-of-service requirements were either nonexistent or brief.

In 51 cases, coverage was confined to employees in certain departments or occupations: For example, to machine printers in textile finishing and dyeing mills, to pressmen in a newspaper plant. More than two-thirds of these cases had length-of-service requirements of 30 days or less.

Coverage in nine cases was confined to key employees, usually selected upon an individual basis with an eye to the importance of the job and the service record of the individual. Plans of this variety included one which covered a small group of key production and nonproduction workers in a garment plant but excluded the bulk of the production workers, and another in an ice-cream factory which covered a small selected group of employees in a number of key skilled jobs during the dull season.

The proportions of workers covered were, of course, highest in the group of plans which permitted all employees to be eligible, and lowest in the plans restricting coverage to employees in specific departments or occupations and to key employees (table 9). Among the 101 plans where al the employees were eligible for coverage, there were 38 where every employee in the establishmen was actually covered by the guarantee; in the remainder of these plans, the minor exclusions o small groups of workers and the length of servic provisions reduced the proportions of workers actually covered, but only in a small number of case to less than 60 percent. Among the 60 plans r stricting coverage to specific departments or occupations or to key employees, generally less than 3 percent of the total number of workers in the e tablishment were actually covered by the guara-tee. A tabulation of proportions of workers covered showing union and nonunion establishments separately indicates a great range in both groups, but with more restricted coverage in the case of the plans in unionized establishments (table 10). This reflects to some extent the influence of the "basic crew" contracts, and the fact that the plans were limited to those parts of the establishments over which the unions had jurisdiction.

TABLE 9.—*Proportion of wage earners covered in currently operating guaranteed wage or employment plans in Bureau of Labor Statistics survey, by eligibility provisions*

Data not available	28	18	10

The proportion of coverage was highest in plans in small employing units, as shown in table 11. Thus, 34 of the 38 plans in which 100 percent coverage was reported were in establishments employing less than 50 workers. There were, however, a small number of plans covering 70 percent or more of the total workforce in establishments or employing units with several hundred or more than one thousand workers. In absolute figures respecting numbers of covered wage earners, 149 of the 188 plans for which information was available covered less than 100 wage earners, 18 covered from 100 to 500 wage earners, 7 covered from 500 to 1,000, and 14, or 7 percent of the total number, covered 1,000 workers or more (table 12).

[1] A guaranteed wage or employment plan embodied in a master contract between a trade association and a union is counted as a single plan, and is classified according to the total number of wage earners in all of the covered establishments. There are 10 such cases.

[2] Includes 2 master contract plans.

[3] Includes 4 master contract plans.

For purposes of comparative analysis of the duration of the guarantees, the Bureau has classified the plans in accordance with the amount of wages or employment guaranteed or advanced, in terms of weeks of full-time or part-time hours or pay. In the few cases in which the duration of the guarantee was adjusted according to a sliding scale on the basis of such factors as wage rate or length of service, the maximum duration of the guarantee was used for the tabulation. The number of weeks of employment guaranteed was chosen as the means of expressing the common denominator because guarantees in terms of number of weeks of employment per year occurred most frequently. The actual wording of the guarantees reflected a wide range of plan and contract terminology. The variety of language used is illustrated by a listing (on p. 13) of extracts from the texts of plans which guarantee substantially the same employment—a full year, at full-time wages.

Almost two-thirds of the plans (128 out of 196) guaranteed employment for a full year at full-time hours or pay (table 13). Most of these arrangements were guarantees of 52 full weeks of employment or pay in the absence of employment; very few were expressed in terms of an annual wage. Eighty-five percent of the plans (166) guaranteed full-time pay for 40 weeks or more. The total of 61,000 workers covered by the 196 plans was distributed in approximately the same manner as the number of plans (table 14).

[1] Data not available for 8 plans.

[2] Data not available for 5 plans.

[3] Data not available for 2 plans.

[4] Data not available for 1 plan.

Most of the guarantees were expressed in term of employment rather than in terms of wage The detailed studies made by the Bureau in 6 cases indicated that this manner of expressio arose largely from the employer's confidence th he could provide the stated amount of work, an where the worker failed to make himself availab for work, no pay was generally given.

Thus far, it has appeared that a major propo tion of the guarantees provided full-time pay f an entire year, and that a large group provid coverage for all employees upon hiring or after a relatively short period of time. A cross-tabulation of these two characteristics provides a method of determining the extent to which full-year guarantees and guarantees to all employees after a short period of time coincided. Table 15 shows the multiplicity of combinations of guarantee and eligibility provisions that were embodied in the plans. For example, of the group of 128 plans which guaranteed full-time employment for an entire year, 39 afforded coverage to all employees upon hiring or within 30 days thereafter. The remainder had additional length-of-service requirements, or restricted coverage to employees in "regular" jobs, to employees in specific departments or occupations, or to key employees.

ISTING OF GUARANTEED WAGE OR EMPLOYMENT PLAN CLAUSES, ILLUSTRATING THE VARIETY OF METHODS EMPLOYED TO EXPRESS GUARANTEES OF FULL-TIME ANNUAL EMPLOYMENT

1. The employer agrees to continuously employ__________ union persons * * *. These shall constitute the basic staff and shall not be subject to lay-offs at any time.
2. The tenure of employment of permanent employees shall be 52 weeks in each year without any lay-off whatsoever.
3. For each full year of service after the first year, 2 months of indemnity in case of complete lack-of-work lay-off, or 346⅔ hours of straight time pay in case of partial lack-of-work lay-off, will be added to the indemnity or guarantee until, after 6 full years of service, a maximum of 1 year or 2,080 hours' indemnity or guarantee is provided.
4. All employees shall receive 12 months of uninterrupted employment.
5. All steady employees who come under the scope of this agreement shall be guaranteed steady employment throughout the life of this contract.
6. The basic gang employed by the employer hereunder shall consist of 3 mechanics, 2 helpers and 1 car washer. Each of such men shall be employed by the employer for 2,000 hours during the period of 1 year covered by this agreement * * *.
7. All skilled employees covered by this agreement who have passed their probationary period as hereinbefore set forth, shall be paid on the basis of 52 weeks per year.
8. * * * each of the said members of the said association in the employ of the company * * * shall * * * work not more than 2,000 hours during 50 calendar weeks of the period covered by this contract. It is the intent of the parties hereto that the members of the association shall have 2 weeks' vacation with full pay.
9. Each employee * * * will be offered 2,000 hours of work during the calendar year. In addition to offering each employee 2,000 hours of work, each

employee will be given paid time off at times to be designated by the employer to make this agreement conform to the 40-hour provision in the regular contract.

10. The employer guarantees to the 5 maintenance men named in the contract between the parties, dated November 1, 1941, not less than 48 hours of work, or the monetary equivalent thereof, in every week during the 52-week period which is the term of this contract.
11. It is further agreed that regular employees be employed 52 weeks per year.
12. Whenever the term "steady employee" or "steady employees" shall be used in this agreement, it shall refer to such employees of the employer who are guaranteed under this agreement 12 months work in each year during the period of the contract.
13. A salesman may be discharged upon 2 weeks' written notice by the employer to the union * * * (slack season, however, shall not be deemed a cause or a reason for the discharge of a regular salesman).
14. Said employer agrees to employ said employee as ________ for a term of 1 year from the date hereof, at a weekly salary of __________.

Further examination of the group of cases which provided the most substantial guarantees to the broadest groups of workers shows that they were for the most part cases that involved small or medium-sized groups of workers (table 16), and that more than half of them occurred in wholesale and retail trade (table 17). The proportion of unionized establishments was substantially less in this group than in the entire group of 196 plans.

DISCONTINUED PLANS

A total of 151 plans are known to have operated in the United States and to have been discontinued prior to 1946, including the 96 which were in existence for slightly more than 1 year under the provisions of the Wisconsin unemployment compensation law during 1934 and 1935. The discontinued plans involved total employment of nearl 180,000, of which approximately 3 percent involved the 96 Wisconsin plans and more than 8 percent the plan of 1 large manufacturing concern The reasons for their discontinuance have alread been discussed in an earlier section.

The plans that have been discontinued exhibi no characteristics essentially different from thos of the plans which are still operating. Information concerning the number of wage earners covered under the plans (table 18), the coverag provisions and eligibility requirements of th plans (table 19), and the duration of the guarantees provided (table 20), show the same gener picture that has already been presented with r spect to the plans that are still in operation. As far as industry distribution is concerned, the discontinued plans show a substantial scattering among virtually all of the same industries in which guaranteed wage or employment plans continue to exist (table 21). Aside from the 96 Wisconsin plans, it appears that plans in retail and wholesale trade were discontinued to a lesser extent than in other industries.

EXPERIENCES WITH GOVERNMENT LEGISLATION

Reference has already been made to the 96 plans which operated for approximately 1½ years under the Wisconsin Unemployment Act of 1932, and the fact that no plans at all have come into existence under the guaranteed-account provisions of the Federal Social Security Act of 1935. The provisions of the Fair Labor Standards Act relating to guaranteed wage or employment plans in section 7 (b) (2) have been mentioned, and the Bureau's study has included a specific exploration of the experience with this law.

Twenty companies reported the operation of guaranteed wage or employment plans (eight of which are still in operation, the remainder having been discontinued, largely during the war years) under section 7 (b) (2) of the Fair Labor Standards Act.[2] The number of plans that have fully met the requirements of the law is unknown; none has been the subject of final court determination. In some of the 20 cases, however, there was some question whether the full requirements of the law or regulations had actually been met, (a) because of apparent failure to meet the requirement that the union representing the employees be certified as bona fide by the National Labor Relations Board, (b) because of contract provisions that may not have met the full requirements of the law (a matter which could not be finally determined because the plans had not been officially commented upon by the Wage and Hour and Public Contracts Divisions or ruled upon by the courts), or (c) because of failure (in five cases) to file contracts as required by regulation.

Eight of the companies which took advantage of the provisions of section 7 (b) (2) were included in the Bureau's detailed study of 62 cases. In one case the inducement of the overtime exemption was reported to have been responsible for initiation of the plan, which was sponsored by management. In two, the overtime exemption was reported to have been important in determining management's acceptance of union proposals for guarantee plans. In another, management's desire for overtime exemption and labor's desire for security were reported as equally important motives. Ir the remaining 4 cases, guarantee plans were al ready in effect or about to be put into effect ir October 1938, the effective date of the Fair Labo Standards Act, and were modified to conform t its provisions.

Of the eight guarantees studied, five are still i operation (in only four cases under 7 (b) (2), how ever). One of the former 7 (b) (2) plans wa abandoned because of employee dissatisfaction fo lowing a drop in annual earnings during the years after the plan's inauguration. The earr ings' decline had resulted from operation of th annual hours ceiling, some employees having be laid off as early as the first week in Novembe The second was abandoned because of the dif culty of adhering to the annual hours limit und wartime conditions. The third was abandon because of the general uncertainty of operati any guarantee under wartime conditions. In t latter two cases, some sentiment was reported f eventual reinstatement of a guarantee, althou in both cases union representatives were lukewar about the possibility of the plans again taking t shape of 7 (b) (2) arrangements because of t elimination of premium overtime pay and t absolute ceiling on annual hours of work. In additional case, where a guarantee is still in op ation, 7 (b) (2) provisions were eliminated 1942 because of longer wartime working hours

---

[2] Employers who had filed contracts with the Wage and Hour and Public Contracts Divisions under the provisions of sec. 7 (b) (2) were included in the Bureau's canvass; the Administrator's regulations under the Fair Labor Standards Act require that contracts under sec. 7 (b) (2) be filed with the Wage and Hour and Public Contracts Divisions.

Five of the twenty firms which reported operation under sec. 7 (b) (2), however, were not included in the list of companies that had filed with the Wage and Hour and Public Contracts Divisions.

The best-known of the guarantee plans which has continued to operate under section 7 (b) (2), and the one which covered more wage-earners than any other 7 (b) (2) plan, has been that of Geo. A. Hormel & Co., whose plan antedated the Fair Labor Standards Act. At the congressional hearings on that act, representatives of the firm appeared, to urge the inclusion of a provision which would enable it to preserve its established guarantee; section 7 (b) (2) was framed to allow the continuation of and to encourage arrangements of this kind.

Six of the eight firms which operated under section 7 (b) (2) reported some difficulty during their experience with the plan in balancing man-hours so that the annual limitation stipulated in the law vould not be exceeded. In two of the cases it was ıecessary to lay off employees before the end of he year.

One-third of the 54 employers (of the entire roup of 62 studied) did not invoke the pro-isions of 7 (b) (2) in connection with their uarantees because they were unable to meet re-uirements of the section (either the guarantee rovided more or less employment than the stipu-ated 2,080 hours, or no bargaining unit existed n the plant) or because by the nature of its busi-ess the firm was not subject to the Fair Labor tandards Act. Other reasons for failure to take dvantage of the provisions of 7 (b) (2) reported ess frequently were union opposition to elimination of premium overtime payments and the impossibility of controlling employees' annual hours to conform to the 2,080-hour limitation. A large proportion of the employers who did not invoke section 7 (b) (2) were not acquainted with its provisions.[3]

Chiefly because of unfamiliarity with its provisions, very few of the employers or union officials interviewed had suggestions to make for improvement in the provisions or administrative interpretations of section 7 (b) (2). Three employers suggested the removal of the 2,080-hour ceiling on hours, and the substitution of an annual overtime penalty provision for hours beyond this point. Four suggested that the provisions of 7 (b) (2) be made applicable to nonunion as well as to union employees. It was also suggested that the securing of interpretations or rulings on the legality of guaranteed wage proposals from the Wage and Hour and Public Contracts Divisions be facilitated and that such action be taken before contracts were signed or went into effect. Two employers and one union official suggested that in addition to an annual guarantee, the section provide for a guarantee of minimum hours per week. In general, union officials were reluctant to consider giving up premium overtime rates for a guaranteed wage or employment plan.

---

[3] No special reasons for not utilizing 7 (b) (2) were reported by the employers who had filed contracts with the Wage and Hour and Public Contracts Divisions but had not, in fact, operated under guaranteed wage or employment plans.

ECONOMIC ANALYSIS OF GUARANTEED WAGES

Bulletin No. 907

A reprint of Appendix F from Guaranteed Wages: Report to the President by the Advisory Board, Murray W. Latimer, Research Director

---

PREFACE

Upon the initiative of the Advisory Committee of the Office of War Mobilization and Reconversion in the study of guaranteed wage plans, the Bureau of Labor Statistics commissioned Professors Alvin H. Hansen and Paul A. Samuelson, of Harvard University, to prepare an economic analysis of guaranteed wages. This report was designed to supplement the description of guaranteed wage plans (Appendix C of the OWMR report and also reprinted separately as a Bureau bulletin), prepared by the Bureau for the Office of War Mobilization and Reconversion, and the exploration of the practical possibilities and problems in the extension of guaranteed wages, prepared by the Guaranteed Wage Study staff of the Office of War Mobilization and Reconversion. It appears in the Final Report of the Advisory Board of the Office of War Mobilization and Reconversion as Appendix F.

The present report is an economic analysis of the potential effects of guaranteed wage plans on the economy and the relation of guaranteed wages, if widely adopted, to economic security, business cycles, and the pattern of resource uses.

In accordance with arrangements described above, the Bureau of Labor Statistics also commissioned Professors J. M. Clark, of Columbia University, and Edward S. Mason and Sumner H. Slichter, of Harvard University, to comment on the analysis by Professors Hansen and Samuelson. These comments are included in the report.

The views expressed in all cases are those of the authors.

APPENDIX F—ECONOMIC ANALYSIS OF GUARANTEED WAGES

I. INTRODUCTION

World War II brought full employment to the American people. The coming of peace holds forth the promise of a high level of job opportunities and production demand for some time to come. But no one can today forget how in the dozen years before Pearl Harbor the American economy was plagued with widespread unemployment and idle machine capacity—with an attendant loss of money income to all classes of society, and a reduction in human living standards so calamitous as to threaten the foundations of our democratic way of life. It is now abundantly clear that involuntary idleness cost the American people the equivalent of some $300,000,000,000 of real income in the decade prior to the war. The tragedy, suffering, and frustration of the depressed 1930's will not, and need not, be permitted to recur.

It is not too much to say, therefore, that stability at high levels of employment and production will continue to be the number one domestic economic goal of all the community—business, abor, agriculture, and the Government.

Paradoxically, the United States, one of the youngest and most vigorous of all advanced na-ional economies, seems throughout much of its recorded history to have experienced among the highest rates of unemployment of all the nations of the world. In the great depression following 929 our percentage of unemployment exceeded hat of all other nations, not even being surpassed y the German Weimar Republic. In the recov-ry years just preceding World War II we barely regained the 1929 level of real output, having wasted in unemployment a decade of potential mprovements in our standard of living.

Even before World War I, the percentage range f unemployment in this country seems to have run bout double that of a country like Britain. In dition to having greater amplitude of cyclical uctuations (and somewhat more frequent business cles), the American economy has also been characterized by far greater seasonal swings. Besides, there is some evidence that the range of cyclical variation has been getting worse rather than better in the course of recent decades.

No single line of attack can be relied upon in the battle against depression. In addition to a full employment program, with its many-sided and continuing policies, the Government must be prepared with its social security and welfare measures to ameliorate the human burdens of unemployment. Nor can business, agriculture and labor stand by, passively relegating to the public authorities all responsibility and action designed to promote over-all stability in jobs and production.

One device aimed at mitigating the instability of production and pay rolls is the policy of guaranteed wages. It is the purpose of this report to give an economic analysis of proposals which have been put forward under this general heading.

BRIEF HISTORY OF GUARANTEED WAGE PROPOSALS

The programs initiated by private enterprise to moderate irregularities in production and employment actually antedate by well over a quarter of a century the explicit acceptance by Government (in the Employment Act of 1946) of its responsibility to combat depressions. Particularly after the sharp 1921 post-World War I recession in pay rolls and production, various forward-looking corporations began to institute voluntary wage guarantee plans of one sort or another. Others, without explicitly guaranteeing wages or employment, made strong efforts to smooth out the pattern of their operations so as to provide more continuous annual employment.

Some of these plans may have involved overambitious altruism. Others may have represented ill-conceived paternalism, covertly directed against the organization of unions and the development of collective bargaining. In any case, most of these schemes were short-lived, many foundering on the rock of the great post-1929 depression. Does this mean that they were failures? Not necessarily. In an era when governmental unemployment insurance had not yet been enacted, these plans often aimed at softening the burden of unemployment for at least a limited time. They served as a first wall of defense against depression; the fact that these bulwarks were breached does not mean that they were not of considerable value. Also, in all fairness it should be said that the enactment of governmentally-provided unemployment compensation reduced the pressing need for the continuation of some of the plans.

While the great depression of the early 1930's spelled the end of many of the earlier guaranteed wage plans, it at the same time emphasized in the minds of everyone the great need for job security. And during the recovery years of the last decade, an increasing number of additional companies initiated new guaranteed wage plans.

Organized labor—in part stimulated by the late Franklin D. Roosevelt—begin to develop an interest in wage guarantees during the years just prior to World War II. At the present time, many guaranteed wage programs are embodied in management-labor collective bargaining contracts. Many unions in industries not covered by such contracts have indicated an intention to explore the possibilities of this device.

ORIGIN OF PRESENT STUDY

In 1944, at the peak of the war effort, several labor unions presented a request for a wage guarantee to the War Labor Board. The War Labor Board ruled against the establishment at that time of so important a new precedent in American labor relations. On the occasion of their refusal to grant the United Steelworkers' request, the board members indicated their interest in the proposal, and recommended that the whole problem be given careful study. Early in 1945, President Roosevelt requested that the Advisory Board of the Office of War Mobilization and Reconversion make a study of guaranteed wage plans as a means of regularizing production and stabilizing employment. In making its investigation into the whole problem of guaranteed wages, the OWMR proposed:

1. Examination of specific experience with guaranteed wage plans.
2. Analysis of methods and possibilities of regularizing production and stabilizing employment.
3. Inquiry on cost of various types of wage guaranties.
4. Analysis of economic effect of guaranteed wages.
5. Examination of relation of guaranteed wage plans to other economic measures also intended to stabilize or increase the national income.

In connection primarily with the last two of these points the authors of this report have been asked to make a general theoretical analysis of the economics of guaranteed wages and its relations to other policies. In doing so, we have not considered it fruitful to attempt a review of the voluminous literature on the subject, nor to present a well-rounded factual and quantitative picture of the status and prospects of guaranteed wages. This we can best leave to others. Early in our investigations it became clear that the greatest service we might hope to render lay in bringing under analysis and focusing attention on certain relatively neglected—but crucial—aspects of the problem.

Perhaps most important of these is the need for a critical examination of the repercussions of guaranteed wages upon the level of aggregate demand and upon the business cycle. Hardly less important is an examination of the economic principles and patterns of pricing which society needs to keep in view in order to achieve the most efficient use of our human and capital resources, the reduction of wastes of unstable production, and the equitable distribution of the burdens of unavoidable idleness. These two motifs—business cycle and aggregate demand aspects of guarantee wages, and efficient, equitable use of our nationa resources—run through all our analysis, not onl in their relationships to each other, but als against the background of other public and privat economic policies.

We have not considered it our primary responsibility to spell out in any detail a specific progra of action. We have been primarily concerned wit general economic analysis. In chapter VI we d put forward certain recommendations, which w believe represent policies which are economicall sound in the light of our analysis. Needless to sa these recommendations—and indeed all of o judgments and findings—are put forward only our own opinions as individual citizens and economists. They do not necessarily represent the opinions of the Advisory Board of the Office of War Mobilization and Reconversion, or the Washington Research Staff under the direction of Murray W. Latimer. In part our recommendations overlap or are similar to those in Mr. Latimer's final report.[1] It is a pleasure to acknowledge here the stimulus of discussion with him and his staff, even though we were not always able to agree fully upon final formulation of principle and emphasis.

DESCRIPTION OF GUARANTEED WAGE PLANS

Here at the beginning it is well to ask exactly vhat is meant by "guaranteed wages." No simple nswer can be given because of the extreme variety f plans that one company or another has intro- luced under this general heading in the last quar- er of a century. At the one extreme, we observe vhat is little more than a pious declaration of the ompany's intention to make efforts to stabilize its roduction so as to provide steady jobs and in- omes. At the other extreme, a company may have gned a legal collective bargaining contract with union agreeing to guarantee 45 or even 52 weeks work per year to almost all of its employees.

Even the three best-known plans associated in e public's mind with the guaranteed wage—those the Hormel, the Nunn-Bush, and the Procter Gamble companies—differ materially in form d substance. Because there are so many descrip- ns of the various guaranteed wage plans avail- le, we do not propose to discuss here (except very efly) the different features involved in such ns, preferring to refer the reader interested in ails and in particular concerns' plans to the uminous literature on the subject.[2]

3y a guaranteed wage plan, we shall not neces- ily mean an annual wage plan. Conceivably, the employer's commitment to maintain workers' incomes might be for longer durations than a year—for example, over the whole of the business cycle. More often guaranteed wage plans are set up with a calendar year as the fundamental unit of time. But not infrequently, a firm may wish to guarantee employment for only 6 months or only for the whole of a season. Our analysis will apply also to such plans, but we exclude from our consideration programs concerned with insuring only a full week's work or any period less than, say, a quarter of a year.

The form of the guarantee may vary considerably: Some firms may insure a certain number of weeks' employment at unspecified job assignments and wages; or more often, there may be a guarantee of a certain number of specified pay checks—even if the concern should find that it has no duties for the workers to perform. Usually, if a firm has bound itself to continue a worker's income, it will cast about for some work for him to do, even if it is of a low-productivity character or of a currently unprofitable and unremunerative sort. But where even this is lacking, the corporation agrees to maintain the incomes of the workers who are included under the guarantee. The guaranteed wage becomes in this case the precise equivalent of 100-percent unemployment compensation, maintained for the duration of the guarantee.

Often the plan provides for the maintenance of income payments from week to week at a steadier rate than hours of employment, the overtime of some periods being balanced against the hours of underemployment through other weeks of the year.[3] Under the Fair Labor Standards Act, any weekly hours of work in excess of 40 are usually to be paid for at a one-and-a-half overtime rate; but that act did provide for a partial relaxation of such penalty overtime rates in cases where a collective bargaining contract is in force guaranteeing certain minimum hours of total yearly employment.

Not infrequently, guaranteed wage plans are associated with various wage-incentive or profit-sharing programs. In addition to the steadily maintained periodic wage payments, there may

he most comprehensive study prepared to date is the Latimer t. The National Industrial Conference Board, the National ciation of Manufacturers, and Brookings Institution either issued or will shortly issue studies on various aspects of guarantees; and Joseph Snider's book, The Guarantee of and Wages (Andover, 1947), is just out. See also the bib- phy prepared by the U. S. Department of Labor, April 1945, ed "The Guaranteed Annual Wage and Other Proposals for ying the Worker's Income: Selected References," and the ar book by J. Chernick and G. Hellickson, Guaranteed An- Wages (University of Minnesota Press, 1945).

[3] Some companies will lend their workers money in periods of underemployment, payable in subsequent periods of brisk employment. Such wage-advance schemes are related to, but distinct from, the guaranteed-wage plans discussed in this report.

also be supplementary bonus or wage payments at longer intervals of time. The total remuneration of the workers may be geared to their productivity, to corporate profitability, or to the value of production and sales.

So much for the form of the plan, whether it (*a*) guarantees employment, or (*b*) guarantees wage income, or (*c*) involves profit-sharing and various "flexible-wage" features. Equally important are the other various features and limitations of the guarantee, such as the following:

(1) Limitation of coverage. What workers are covered? Are only those who have been employed 2 years, 1 year, or 6 months covered? Or are only workers of certain skills and departments covered?

(2) Limitation of weeks per year. Are a full years' work and income (2,080 hours per year, 52 weeks at 40 hours per week) guaranteed? Or are only, say, 45 weeks of work guaranteed?

(3) Limitation on duration of guarantee. What is the duration and legal character of the guarantee? One prominent plan guarantees 48 weeks per year of work to all of its employees of more than 2 years' standing, but the guarantee is a unilateral one which the company reserves the right to discontinue at any time it may wish to do so. Other guarantees may run from the first of the year to the last, and may be embodied in a collective bargaining contract with a union. Still others may be binding upon the company, but terminable after it has given a year's or 6 months' notice.

The possible costliness, benefits, and other quantitative economic effects of guaranteed wages all depend very much upon the type of guarantees which are adopted—upon their degree of coverage, the hours guaranteed, and the duration of the guarantee. To avoid a tedious catalog of the various plans that are conceivable or now in force we shall find it convenient to outline a few possible guaranteed wage plans, in terms of which our exposition may be facilitated. This does not imply any approval of the particular details embodied in these examples. They are set out simply as hypothetical cases:

Example 1: For each calendar or fiscal year, the company agrees—in a legally or morally binding fashion—to provide some number of weeks, say 45, of full-time pay (or its equivalent spread over the year) to a specified group of workers, selected by seniority or length of previous service. The contract or agreement may, or may not, be renewed for the following year and its coverage and hours of guarantee may be altered, provided notice to that effect is given at least 3 months prior to the end of the contract year.

In this case, if the corporation encountered a sudden slump very early in the year it might be obliged to incur the costs of maintaining income for a period of almost a year. On the other hand, if the decline in its sales came late in the year, the company might be able to reduce its pay roll in very short order.

It would run the risk of having to maintain, on the average, substantial wage payments for something like 6 months after a decline in its revenues.

Example 2: This is the same as example 1 except that the contract or agreement does not run from the beginning of one fiscal year to the beginning of the next. Instead, the guarantee runs on indefinitely—until the company gives 12 months' notice of its intention to discontinue the guarantee or change the extent of its coverage.

One could imagine a plan identical to example 2 except that the period of termination notice i reduced to, say 6 months.

Example 3: This could be like either of th above two plans, but with the extra limitation tha the employer's wage liability to workers laid of should never exceed in any year, say, 10 percen of the guaranteed pay roll. In most years, thi would, in fact, provide 100-percent income securit to all workers. But in a very bad year, when th number of idle workers became very high, then th employer's liability would have an upper limi In this event, the laid-off workers would have t share in some manner the amount available f wage payments within the limitation of the percent liability.

Obviously all sorts of variations could be a tached to each of these illustrative cases. All thr examples have this much in common: They e hance the job and income security of workers for least a limited time into the future; and they i volve the employer in the risk that, for a limit time at least, he may be obliged to maintain wage outpayments even if his sales revenue fa off sharply. However, the employer has not obligated himself to incur unlimited losses for an unlimited period; after the period specified under the terms of the contract, his guarantee terminates; and, of course, after these same periods of time, the worker may find himself jobless and without a current pay check.

One point requires notice and emphasis at this place. While the letter of the guarantee may specify that the employer's liability ends after the date of termination, management and unions both are well aware that there will be considerable social pressure upon the employer to renew his uarantee and to maintain employment longer han specified in the contract. This explains why nany financially strong companies, who do not loubt their own ability to finance guaranteed vages for the first year of a serious depression, are ievertheless reluctant to offer even a limited guarntee. Not without cause, they fear that such a imited commitment may put them on the spot fter the period of guarantee is over. They realize iat even those companies which guarantee nothig are under more or less powerful internal and xternal pressure to minimize lay-offs; but they so realize that such pressures are not brought to sharp a focus as would be the case under a guariteed wage plan. In the following discussion e shall, on occasion, have to go beyond the legalis letter of the guarantee commitment to the furer economic implications.

SOME PRELIMINARY OBSERVATIONS

Before discussing in detail the outline of our nomic analysis in the following chapters, we ll do well to clear the air with a brief statent of certain fundamental preliminary conclns.

First, the guaranteed wage is not a cure-all for problem of business cycle unemployment— could it ever approach near to being one. aggerated claims, overstating its importance advantages, do more harm than good. At the y beginning, we wish to state for the record— nkly and explicitly—that if it ever had to come choice between guaranteed wages and other ortant depression and anticyclical public and ate policies, such as our system of unemployment insurance,[4] our social security programs, or fiscal and monetary policy, then it would be guaranteed wages that would have to be rejected. We do not wish to be misunderstood. As will become abundantly clear from the pages that follow, we do not see any necessary conflict between guaranteed wages and other needed Government policies. On the contrary, it is to be hoped that guaranteed wages can be integrated with unemployment insurance so as to strengthen income security. Also, it is our view that guaranteed wages can be financed so as to contribute something toward moderating the excesses of boom and slump in the business cycle.

Second, although the primary motivation for guaranteed wages comes from wage-earners' fear of business cycle unemployment, our studies lead us to the following somewhat paradoxical conclusion. In a world of high effective demand and purchasing power, where there is no problem of chronic or depression unemployment—in such a world, guaranteed wages might make its greatest contribution: by stabilizing seasonal and other short rhythms in production and by equitably allocating the economic burden of the residual amount of unavoidable idleness and unemployment. This conclusion emphasizes all the more the importance of a full employment program, within the pattern of which the guaranteed wage can play a significant role. Under the present system of lay-off on short notice, the employer finds himself with insufficient financial incentive to undertake the costly efforts which are necessary for thoroughgoing stabilization. What are truly overhead costs to society often appear to the employer as avoidable variable costs, with the result that enlightened competition does not lead to the economically most efficient use of resources.

The view that the single individual firm, even a large one, can by good intentions and clever policies substantially contribute to solve the problem of the business cycle, we are compelled by economic analysis and all the available empirical data to discard in the beginning. No one enterprise is secure enough or powerful enough to withstand and modify the great swings of general business activity.

---

[4] There are, to be sure, many technical imperfections in our present unemployment insurance system: inadequacies of integration and uniformity between states, insufficient benefits in relationship to reserve accumulations, perverse cyclical aspects of merit or experience rating, etc. These should be remedied by legislation and practice. They should not be used as an excuse to attack unemployment insurance, or as an argument for substituting guaranteed wages or any other alternatives in place of unemployment insurance.

In our judgment, there is scarcely more validity in the hope that gradually, by more and more firms voluntarily extending the scope of their stabilization activities, we shall approach finally to a condition of continuing high employment income and production. As we shall show later, there is every good reason for looking with approval upon a redoubling of the efforts of management, on its own initiative, toward ironing out its employment and production fluctuations. And when a considerable number of firms have carried through bold, imaginative, and well-conceived stabilization programs, considerable progress will have been made toward reducing the costs of economic idleness. But by far the greatest progress that will have been made is likely to be in connection with unemployment arising from seasonal and other rhythms of business activity of shorter duration than that of the business cycle.

From a dispassionate appraisal of the efficacy of guaranteed wages, the device would appear to be, by itself alone, a weak reed upon which to rely in an attack on such widespread unemployment as our economy has encountered in recent years. Indeed, it would be nothing less than tragic if, by management initiative or governmental and trade-union pressure, an ambitious program of guaranteed wages was undertaken without at the same time instituting other more important programs of government and business designed to promote high and stable levels of production, income and employment.

While it is conceivable that an ambitious program of universal wage guarantees would diminish the intensity of minor fluctuations, such as occurred in 1924 and 1927, there is danger that it might be financed in a manner that would intensify such deep and cumulative recessions as that of 1929. The relationship between guaranteed wages and the sharp recessions of the 1920–21 or 1937–38 type are by no means easy to appraise. If other governmental measures were not instituted to cope with depressions, sober quantitative appraisal of the relationship of pay rolls to corporate net worth shows that insolvency and bankruptcy could well be the price of any guaranteed wage program which was not carefully limited in its coverage and duration. Business, even large business, is not the master of its fate where the business cycle is concerned.

On the other hand, we cannot be content to accept the chaotic status quo. For if we look at, say, the automobile industry, which very properly stands out in the public's mind as typifying the very essence of our industrial society, the picture we see is far from reassuring. Automobile production is an efficient undertaking, paying higher wages than the rest of the world and yet through greater productivity able to undersell all other countries on a free-trade basis. It is and has been a relatively profitable industry. An important part of its total output is under the control of three giant corporations, each of which has presented typical chapters in American industrial life: the self-contained growth of Henry Ford's great enterprise, the evolution after World War I of the vast General Motors Corporation, and the post-1929 emergence to full stature of the Chrysler organization. In addition the recent war has placed the remaining smaller independent producers in a comparatively favorable financial position.

But if we look more closely we see that it is an industry that lives dangerously. Stocks of finished cars and of parts and raw materials are literally measured in terms of days and weeks of production rather than in terms of months and years. The continuance of production hinges on a precarious scheduling of thousands of components produced in hundreds of separate plants. This elaborate division of labor and interdependence, which we hardly notice in ordinary times, makes for efficiency but at the cost of vulnerability—as was revealed in the postwar disorganization of the industry.

Despite the fact that the use of automobile services, as measured by passenger rides or gasolin consumption, fluctuates only moderately over th year and even over the ups-and-downs of th business cycle, the flow of automobile productio proceeds in much more fitful jerks and starts, a dictated by the vagaries of consumer and deale ordering and the march of the business cycle. I consequence, the employment record of the industry—the job experience of the workers attache to the industry—can almost be termed a shockin one. Even in relatively good times workers often spend considerable time waiting to be called back to their jobs. In depression the production of autos and trucks may decline to a quarter of the prosperity levels.

To say that the situation is a shocking one is not to imply that any one group of individuals or organization is to blame or that the record of this industry is worse than that of many others. Different companies have at various times made determined efforts to iron out their fluctuations in production. The whole industry together has attempted to reduce seasonal variations by means of rescheduling the time of introducing new models and of holding auto shows. The results have been disappointingly meager. Clearly the historically developed institutional structure of the industry and of our unstable American economy must be blamed for the unsatisfactory character of the industry's performance with respect to production stability. Under the existing set-up no one company has the financial incentive or ability to provide steady jobs and income.

For a cure to the fluctuations in auto production over the business cycle, we must properly look elsewhere. But it is not too much to hope for, and to ask of management and labor, that measures be taken and practices be altered to moderate the incidence of irregular and seasonal employment and of economic idleness. This may require many far-sweeping changes in the organization of the ndustry: increases in inventories and storage facilities, limitation on undue coddling of consumers' desires with respect to modification of style nd model changes, perhaps acceptance of lower ourly wage rates in exchange for higher annual arnings. Conceivably, such a program of horough-going seasonal stabilization might even aise costs and prices to the consumer. None of hese measures would be easy and none would be ostless. But in a real over-all sense the costs re less than those of idleness under the present egime of instability, where the burden falls upon ose least able to bear it, the workers.

Is it too much to hope that in the not too distant ture all parts of the industry will look back and onder that the present day wastes of idleness ere even for an instant tolerated? We believe ot. But in taking this viewpoint, we do not mean to imply that such a happy state of affairs will come into existence simply by forcing the industry, through Government legislation or collective bargaining pressure, speedily to guarantee wages for substantially all employees. Unless a general, many-sided attack is made upon the problem of business cycle stabilization, together with a step-by-step industry-wide attack upon seasonal instability of production, guaranteed wage plans are likely to be so costly as to be doomed to failure.

It is this dilemma—that the present day deeply-rooted wastes of instability are economically intolerable but cannot simply be legislated out of existence—with which this report is concerned.

PROPOSED OUTLINE OF ANALYSIS

Of the five divisions of the study of guaranteed wages mentioned earlier, our report is naturally concerned with the final two: an analysis of the economic effects of guaranteed wages, and an examination of such plans in relation to other economic measures designed to stabilize or increase the national income. Such an analysis is a necessary supplement to a study of specific experience in different concerns and different industries.

The whole is more than the sum of its parts. Particular firms may have success with the guaranteed wage, in part because they are the only ones offering workers its advantages. The total economic impact of such plans might be negligible, or if overly ambitious or too "soundly" financed, the device might even prove harmful to over-all stability. If wage guarantees discourage investment commitments and if firms are induced to stabilize their employment at low levels in order to minimize lay-offs, the problem of reaching and maintaining full employment could conceivably be aggravated. Or if guaranteed wages had the effect of attaching workers to a single firm in subsidized idleness or inefficient production, then under certain circumstances national output and productivity might suffer.

Under the present wage contract, do the apparent money costs of hiring or laying off labor truly reflect the overhead social costs to society of maintaining the workers' standard of living? What should the relationship be between prices and wages in order that economic resources may be used most efficiently?

Perhaps more important still is the question of how guaranteed wages—on a limited or on a wide scale—affect the over-all level of aggregate demand. Would the mere act of guaranteeing employment create attitudes and behavior patterns sufficient to realize its stated objectives? We all know in a rough way that jobs make markets, and that markets for goods make jobs. Would the widespread commitment to maintain jobs automatically create the purchasing power necessary to make good such a commitment? Or to put the matter in another way, would the balance of aggregate demand in relation to our productive potential be improved; and would the basic factors causing fluctuations in investment—factors which underlie the business cycle—be compensated for?

Each one of these questions requires detailed over-all economic analysis. Each one leads inevitably to a consideration of other economic policies aimed at promoting economic security and stabilizing business activity.

In the chapter immediately following this introduction, we undertake to analyze the true economic cost of different kinds of idleness: to inquire how its amount is to be measured, to investigate how its burden is distributed between wages and property-returns, both in and outside of the industry concerned, and to examine the adequacy of incentives toward regularization.

Then in chapter III the interrelationships, comparisons, and contrasts between guaranteed wage programs and other public programs such as unemployment insurance and full employment programs are discussed.

Chapter IV presents an economic analysis of the effect of guaranteed wages on the level of and fluctuations in aggregate demand. The results are found to differ depending upon whether the guaranteed wage program impinges on a society which is highly cyclical and fluctuating, or is reasonably stable at either a low underemployment or a high full employment level. In this analysis the effects of private reserve financing in contrast with the "pay-as-you-go" method of financing are examined.

While the problem of unemployment was quantitatively most pressing before the war, it cannot be permitted to overshadow the ever-present task of seeing to it that resources shall not only be used, but used efficiently so as to contribute toward the maximum satisfaction of individual and social economic wants and needs. Chapter V is concerned with the effects of guaranteeing wages upon the pattern of resource use and upon the structure of prices, wages, and costs. Here again it is necessary to distinguish among the different kinds of economic societies into which the guaranteed wage plans are introduced.

In chapter VI, we make a number of policy recommendations growing out of our analysis. Such guaranteed wage plans as may be introduced should be set up only after the possible dangers and limitations have been thoroughly canvassed. When this has been done, we believe that, under safeguarded procedures, the guaranteed wage can be made to contribute to a better and more efficiently functioning economic order, and that inducements such as those recommended in chapter VI looking toward more widespread experimentation and expansion are justifiable.

II. ANALYSIS OF THE ECONOMIC BURDEN OF IDLENESS

In this chapter we shall undertake to analyze in some detail the precise nature of the economic costs of unemployment and idleness. In the course of our discussion it will become clear that the problem of irregular production is more than the problem of general cyclical unemployment, although the quantitative magnitude of the latter has been such in recent years as to dominate our thinking and attitudes. To the degree that we are able to avoid serious breakdowns in the years ahead, problems ("labor mobility" for example) which seemed—and were—unimportant against the background of depression unemployment, will take on a new significance. Thus we are concerned not only with depression unemployment, but with the problem as a whole, including daily, weekly yearly, and longer-term irregularities and fluctuations in business activity, many of them avoidable

SOCIAL VERSUS PRIVATE COSTS OF IDLENESS

But first let us note that the present system o hiring, employing, and paying labor is only one o many conceivable alternatives; and one which became widespread even in our own economy onl in the last century. Before industrialization ha impersonalized our economic relations, it was probably the rule more often than not for a craftsman's helper to be hired by the year or season. Often, barring discharge for personal incompetence, the worker could even count upon some measure of job security and income maintenance even through hard times, the employer and employee tightening their belts together.

Even today in agriculture and some branches of small industry, the same relationship often prevails. And throughout all industry, large and small, executives and white collar workers are in ood part assured of employment over all of the ear and through most of the business cycle. It s perhaps not too hard to imagine an economic ystem in which the wage contract with all emloyees was more nearly like that with executives nd white collar workers than like the present revailing mode of wage payment and tenure.

Let us, however, consider the prevailing form f the wage contract and analyze its economic efects for whatever they may be. An industry with igh seasonality may hire its workers for 7 or 8 onths, leaving them idle during the off-season. imilarly, a concern sensitive to cyclical fluctuaons may take on many new workers during the pswing of the boom, and conserve its resources ring the depression by curtailing its wage yments.

Still, as was pointed out so clearly a score of ars ago by Prof. J. M. Clark in his masterly udies in the Economics of Overhead Cost:[5]

> In a more general sense, however, there is a minimum maintenance of the laborer's health and working capac- which must be borne by someone, whether the laborer rks or not: that is, if it is not borne, if the maintenance not forthcoming, the community suffers a loss through deterioration of its working power which is at least ivalent to the cost of maintaining the laborer. Thus burden is there in any case: it cannot be avoided. m this point of view it appears that a large part of cost originally counted as wages represents an overd cost which the laborer is responsible for covering best he can, just as the employer is responsible for ering the overhead costs on account of capital. How-, if the laborer fails to cover it the community does escape the burden, and it is ultimately borne by inry in the shape of reduced productive power and aged morale. And thus it comes back to the employer ny case.
>
> * * * The reason why the expenses of production, some of them, normally vary in proportion to output is simply because the terms of the wage contract are drawn in that way. The employer leaves the wage earner to care for his own overhead and the terms of the contract are not scientifically adjusted as, for instance, the contract for electric current is sometimes adjusted to the overhead costs of the ultimate producer. It may be that we shall find that our general system of wage payment is thoroughly unscientific and that a more scientific system may operate to improve the steadiness of employment in much the same way in which scientific rate systems have been used to increase the regularity of use of electric power plants (p. 16).

The fundamental discrepancy between true social costs of unemployment and apparent pecuniary private costs is of course accentuated by the form of the present wage contract. Without as yet going into the merits of such a proposal, let us suppose that by voluntary action or collective bargaining arrangements, firms were induced to provide income or work for their employees throughout all the year or all the business cycle. Then not only would the burden of the worker's maintenance be spread differently between the workers and the employers in the industry in question, and among the other workers and employers who make up the community at large, but in addition the use which the employer would make of labor might be different. Moreover his production or sales decisions might very probably be appreciably affected.

Today in a depression, a firm will for the most part not hire a man unless in some sense it expects to receive in value a return commensurate with his full wage. Not so does it act with respect to the machinery it owns. If, because of slack times, a piece of machinery can produce only a fraction of the value for which it was originally purchased, the firm will not thereby leave it in idleness. On the contrary, so long as the machinery can produce anything above its costs of operation (including of course any extra deterioration engendered by use) it will pay the firm to utilize the machinery.[6]

---

[5] ohn Maurice Clark, Studies in the Economics of Overhead (University of Chicago Press, Chicago, 1923).

[6] To some degree, therefore, we might expect some differences in entrepreneurial behavior of firms in such rare industries as shoe manufacturing, where much of the equipment is rented on leases of relatively short duration. Even here the changed form of the contract, from ownership to leasing, has important repercussions on how the various parties share the total social economic burden. An important qualification to the theoretical notion that firms do in fact disregard all truly fixed or overhead costs is indicated later. Often, in imperfectly competitive markets, they use full-cost considerations in their pricing—for rational and irrational reasons.

THE ECONOMIC COSTS OF IDLENESS

If an industrial worker has employment only 8 months a year and must lay off for 4, the true cost or economic burden to society is the amount of production which he is prevented from producing during the 4 months of idleness. Generally speaking, we should expect this to be roughly equivalent in value to the wage income that the worker loses by unemployment plus an additional wastage of capital and nonhuman resources as a result of the instability of production. Similarly, if a longshoreman works only a few days a week, the important costs to society are the foregone value of production and income on the days of enforced idleness.

Our earlier quotation from J. M. Clark gives an understatement of these true social costs, because the emphasis there is placed upon the necessary maintenance expenditure of the worker during periods of idleness. It is not improbable that an industrial worker capable of producing $3,000 worth of output per year might, by practising stringent economies, be able to maintain himself and his family with their health, skills, and (more doubtfully) their morale intact on an expenditure of $2,000 per year. Nevertheless, the true cost of a year's idleness of such a man is still $3,000 and not $2,000. And even if science were able to devise ways of costlessly putting men on ice, to hibernate during slack times like bears during the winter, the costs of idleness would still be the same.[7]

We feel it necessary to expound at some length these almost trite, fundamental economic principles because only in this way can a number of current misconceptions and distorted emphases be avoided. Thus, it is quite false to think that the social cost of instability would disappear completely if the employer were made to pay the workers' salary during periods of lay-off. Actually, this might be a highly desirable policy, because the worker may be least able to bear the cost of idleness; and because society may deem it desirable for the employer to shoulder part of the cost in lower business profits, or wish the burden to be shifted in part forward to consumers and the general public in higher prices, or wish the burden to be shifted backward in reduced wage rates for all workers (including those who continue to hold steady jobs). But if the workers' incomes were maintained, though they are idle, the social wastage of productive resources would still be borne by society as a whole.

The total social cost is not changed in real product terms by different modes of sharing the burden of idleness. The social cost for the community as a whole will remain unless greater stabilization of jobs and production is achieved. It is not enough merely to transfer the burden from Peter to Paul. (Perhaps we should not say "merely" since it does make a great deal of economic, political, and social difference just how equitably or inequitably economic burdens are shared between the Peters and the Pauls of different economic levels.)

We do not deny that different modes of sharing the burden can have considerable repercussions on the total amount of the burden. For example, shifting part of the burden of depression unemployment from the workers to the Government may, depending upon the method of finance, reduce the amount of unemployment. Or making industry bear the costs of certain kinds of seasona irregularity of employment may provide just th stimulus necessary to cause the introduction o effective stabilization programs.

In brief it is the effective carrying out of productive employment rather than merely the payment of wages that reduces the social costs of idleness and instability. Income maintenance without productive employment stabilization is only half-way measure which transfers the econom burden of waste and minimizes its social impac but fails to diminish it.

When, as above, we speak of the economic cos of idleness, we must be careful to distinguish b tween various kinds of idleness. Of course, no o can work 24 hours a day. The hours spent in sle are not wasted, any more than is the time spent i leisure on Saturday afternoon and Sunday, or o holidays and vacations. We need not regard ba ball pitchers who go hunting during the weeks following the World Series as wasting their time, any more than we would consider firemen on their way back from a fire or for that matter firemen playing checkers while waiting around for a new alarm, as being unproductive.

---

[7] This is all the more evident if we apply the argument to the less controversial and emotional problem of a nonhuman resource like land. If a 100-acre field neither gains nor loses in productivity by being left fallow for a season, can we say that there are no costs involved in its idleness just because no outlay on maintenance is required? The answer is "No." The potential crop of that year is lost forever. If the land actually goes to weeds and deteriorates through nonuse, the costs are that much greater.

If there has been a real change in society's desire or technology so that the land or worker now has a lower potential economic productivity, then the waste due to idleness is, of course, equal only to his new potential economic productivity.

In other words there are unavoidable cessations of activity which are an intrinsic part of certain productive activities. All cost comparisons are relative. It would be pointless to compare our ac- ual national output with that which could be ob- ained if the laws of thermodynamics were other han they are; or with what we could produce if o one required sleep and desired leisure; or with hat would be producible if the seasons were con- tant. To the extent that work interruptions are navoidable and intrinsic, it will make for clearer hinking if we avoid the term "idleness" and "eco- omic waste."

Also, to the extent that curtailment of labor re- lts in a reduction of human disutility or, what almost the same thing, an enhancement of the ility of leisure—to this extent it would be ob- ously incorrect to regard the resulting loss of onomic output as an equivalent total social ste. Thus, nobody laments the fact that our onomic system fails to provide 84 hours a week work for all, or fails to find work for a subway endant in between stations. There are only so ny activities that human beings can be reason- ly expected to attend to at any one time.

nvoluntary idleness such as is encountered over business cycle or in many highly seasonal in- stries presents little or no saving grace in the n of reduced disutility. Rather does our meas- ng of the cost of idleness by the value of lost put understate the true loss. In addition there n extra psychic loss inherent in unemployment lf. A man thrown out of work against his is not on a vacation. In the present state of society, work under reasonable conditions up ome 40 hours per week and 50 weeks per year ot a curse but a boon and a benefit. The social of transferring a man from frustrating in- ntary unemployment to purposeful productive loyment may even be greater than the value of goods produced.

e may summarize our discussion of the over- conomic cost of instability briefly as follows: The primary economic cost is measured by the loss of national output resulting from unnecessary idleness; (2) in addition there is a secondary cost involved in the individual misery and social disorganization which grows out of idleness itself.

THE COST OF INSTABILITY TO THE WORKER

The intermittently employed worker suffers from instability primarily from the fact that his pay largely ceases during periods of unemployment. To some degree unemployment insurance benefits, home or work relief, and severance pay may help to keep his income from falling below an intolerable minimum; but only to a limited degree, since coverage is incomplete and of limited duration, and rates are deliberately set low in relation to full-time earnings.

It appears in general to be an empirical fact that workers subject to frequent lay-offs over the year and over the business cycle tend to fare badly in terms of average rate of earnings over the whole year and over the complete business cycle. But it is not at all obvious in theory that this should be so. It could be argued, and it is often argued, that competition in the labor market will cause higher hourly rates of pay to prevail in unstable occupations so as to compensate for their unsteadiness of employment. The mechanism bringing this about is supposedly the familiar one whereby workers refuse to go into industries offering less total compensation over time than prevails in those other industries which offer steady, full-time employment; and in refusing their supply, workers cause wages to be bid up in the highly fluctuating or irregular industries.

Before turning to the available statistics upon the subject, let us point out the rather artificial set of theoretical assumptions necessary to achieve this result. Firstly, the cyclical rhythms in activity of the industry in question must be of sufficient regularity so that workers deciding whether to enter or leave the industry can make some sort of an approximate calculation as to the hourly rate which will in the future yield average earnings comparable over time to stable occupations. Perhaps to some extent seasonal (building trades for example) and shorter rhythms are of sufficient regularity to be forecast by the workers to a limited degree, but the vagaries of the business cycle and other fluctuations preclude even this possibility.

Furthermore, there is the second implicit assumption that job opportunities are so plentiful that workers can afford to pick and choose between different industries and occupations. During the past few decades, this has been far from the truth. Often workers have been faced with the choice of accepting precarious unsteady employment, or none at all. However, if high employment conditions should come to prevail, then this second hypothesis would become more nearly true.

Thirdly, an equalization of average earnings through changes in the supply of workers going into different industries implies that wage rates are set in different parts of the labor market by the operation of competitive supply and demand. Actually, and today this is so obvious that we need not elaborate, wages are to an important degree set by the forces of collective bargaining and are a resultant of the pressures exerted by union and management organizations.

Finally, there are always individual differences in ability, training, and opportunity, all of which tend to create inequality in the earnings of different kinds of workers. Even if all jobs were equally stable, we should still expect important, persistent differences in earnings in different fields. How then can we tell what part of the actual reported differences in earnings are due to different degrees of instability of work, and what part to other factors? The answer is we cannot, certainly not with quantitative accuracy.

One thing, however, is clearly apparent from statistics relating to annual hours and earnings in industries characterized by different degrees of cyclical and seasonal variability.[8] There appears to be little tendency for hourly rates to adjust themselves in different American occupations so that average annual earnings over time are equalized in industries of different degrees of instability.

Some of the industries with most intermittent employment—especially those in rural agriculture areas of the South—also have the lowest hourly rates; while some of the highest hourly and weekly rates are to be found in lines of activity which are most stable in employment.

Logical purists may assert that the differences in average earnings over time are all due to other factors; and that hourly rates have adjusted themselves over what they would otherwise have been. not so as to equalize earnings, but so as to compensate for variability of employment. The form of this assertion makes it impossible for anyone either to verify or refute it. But such facts and analysis as have come to our attention incline us to the belief that any tendency for the hourly wage to rise so as to compensate for unemployment is only of a weak and partial character.

By and large, therefore, we incline to the conclusion on factual and theoretical grounds that the primary burden of instability of employment falls upon the worker and his family in the form of reduced average earnings over the long run. In terms of the equity considerations which underlie the modern insistence upon progressive taxation according to ability to pay and upon the socia desirability of keeping up the standard of life o low-income families, placing the burden of unemployment wholly upon the worker represents th least desirable national policy, and one which aggravates to a maximum the onerousness of th given pattern of instability.

It does not follow necessarily from this that th best economic policy to remedy this situation wou be one of raising standard hourly rates to whatever level is necessary to compensate for instability of employment. We do not say this mere because such a solution would involve extreme changes in the present wage set-up of America industry. Grave inequities may often justify drastic action. More important is the consideration that simply raising wage rates without reducing instability and idleness only shifts the burden off the worker's shoulders but may fail to reduce the economic dollar value of waste. This would tend to be true unless indeed there were some valid reason to expect that raising hourly wage rates would by itself tend to reduce the average instability of production. Moreover, we need to consider the relative merits of raising wage rates and of changing the wage contract in the direction of guaranteeing longer periods of employment as means of promoting stable production.[9]

---

[8] The Washington staff of the guaranteed wage study has tried with little success to find occupations which are alike in all important respects except for varying degrees of stability of employment in order to make such estimates. The data examined were: (1) From the Censuses of Manufactures, 1929, 1933, 1935, 1937, and 1939: total pay rolls, numbers of employees month by month and average annual number of employees for selected industries. (2) From Bureau of Labor Statistics: average hourly earnings for industries selected for (1) and studies of annual earnings of employees in selected industries, published in the following issues of the Monthly Labor Review: February 1940, pp. 401–409; January 1940, pp. 172–182; April 1939, pp. 781–788; October 1939, pp. 921–931; December 1939, pp. 1470–1482; July 1937, pp. 29–37; July 1939, pp. 163–175; May 1936, pp. 1333–1335; December 1938, pp. 1393–1408; October 1940, pp. 823–833.

These questions we must defer until chapter V. But there is one aspect of the problem which deserves mention at this point. Under some circumstances raising the hourly wage rate may actually tend to increase the total of idleness—especially where the problem of "casual employment" is involved. By "casual employment" is meant primarily a condition where (*a*) workers are intermittently hired for short engagements, and (*b*) where the first worker who happens to present himself is likely to get the job. A surplus reserve of workers often results from higher rates of pay, especially if there is general unemployment.[10]

This line of reasoning is abstract and oversimplified. It should not be pushed too far. But it does indicate one aspect of reality, and it does ndicate that any policy of raising wage rates hould be accompanied by supplementary policies lesigned to reduce the total pool of unemploynent.

Even if normal annual earnings were maintained n unstable jobs by means of higher rates of pay vhen working, there would still remain the evil f irregular earnings. An ideally calculating inividual could perhaps be relied upon to budget is expenditure in equal amounts throughout the ear; or in occupations subject to much longer ythms, over the whole cycle. But for ordinary uman beings spending patterns tend to follow osely upon their current income, so that uneven come payments result in ups and downs in living andards.

Added to the evil of variability of work and y, there is the attendant feeling of insecurity. ithout some tangible advance guarantee, for ery worker who is actually fired a number of hers may quake in their boots. Living apprensively from day to day, the worker cannot efficiently make financial plans for the future, cannot undertake advantageous long-run commitments with respect to home ownership, life insurance, and other desirable forms of personal consumption and saving.

To be sure, formal and informal seniority practices already serve to ameliorate, in part, the universal fear of unemployment. But there still remains a large residue of insecurity, which, taking the long view, we must regard as partly unnecessary. This shows that there may even be merit in those limited guarantee plans which do not go much beyond explicitly guaranteeing job security to those who already in fact largely enjoy it. The mere announcement effects may be reassuring to some degree.

The question may be raised whether stabilizing employment and income over time and reducing job insecurity will serve to increase or reduce the average propensity to consume out of a given income. The answer to this question, which has a bearing on the problems discussed in chapter IV, depends upon a nice weighing of conflicting quantitative tendencies. On the one hand when people are reduced from a high income level to a lower one, they probably still try to maintain as best they can the higher standard of consumption to which they have become accustomed. Therefore, because of the "ups" in the "ups and downs" of income, there is a tendency for average saving to be lower and the average propensity to consume to be higher than with stable incomes. On the other hand the persistent fear of unemployment tends to cause people to try to save more out of a given income.

He would be a rash man who would venture a confident definitive answer to the question of which tendency is the stronger, no satisfactory statistics being available. Since there appears to be no strong presumption upon either side, we may tentatively cancel out of our appraisal any claim that guaranteeing wages will have stimulating or hampering effects upon saving habits. (To some extent steady wages improve the credit position of workers and enable them to invest in consumers capital goods such as housing and autos. Such an increase in investment implies a higher rate of effective demand.)

Guaranteeing employment to a limited number of employees raises some of the same policy prob-

---

A further drawback to raising hourly rates is that workers er in their lay-off experience according to seniority and other ters.

A classic case is that of the London dock and wharf workers, lyzed almost 40 years ago by W. H. Beveridge in his significant k, Unemployment: A Problem of Industry (1909 and 1930), 07.

lems involved in excessive seniority provisions.[11] Admittedly, we need not argue that everyone must be dragged down to the level of insecurity of the least fortunate. Having granted this, however, we must still go on to point out the possible evil of carrying seniority and wage guarantees to a favored group so far as to create in effect an economic caste system, in which one fortunate privileged group is protected completely from the vicissitudes of economic life, at the expense of throwing the full burden on those left without protection. Some underemployment for all may be preferable to total unemployment for a minority. If there must always be an irreducible minimum of the working force unemployed, it would be far better for their numbers to be made up of a revolving group of different people, with no appreciable group being unemployed for very long. During the 1930's, those who had been unemployed the longest had the greatest difficulty in finding jobs after business demand began to recover. They were beginning to form part of the so-called hard core of unemployables, until the high level of wartime demand melted the core and proved their employability.

This points a possible way out of the dilemma that giving security to the majority may inequitably and cumulatively concentrate insecurity upon an unlucky minority: the maintenance of a high level of over-all effective demand by bold public policies will serve to help those recently hired employees who lack seniority and who cannot qualify for guaranteed wages.

In concluding this discussion of the evils of job insecurity, we must point out that this is not a matter of concern only to the workers involved. The employer is vitally affected by the workers' mental state in this regard. On the one hand, from a realistic hard-boiled viewpoint there is little doubt that fear of losing one's job sometimes acts as a whip to spur the worker on to more efficient production. Fear of discharge for cause certainly acts in this direction. But fear of lay-off is quite another matter, except to the extent that the order of retention of men and rehiring is made to depend upon demonstrated efficiency. Even in the fairly rare industrial situations where labor is in fact laid off in order of inefficiency and rehired in order of efficiency, there is always the counter tendency that tense and insecure workers may over the longer run be less efficient rather than more efficient producers.

Neither of these last points is so telling as the fact that increasingly in modern industry formal or informal seniority rules determine the order of a worker's lay-off, rather than his own effort and productivity. No worker feels that the chances of retaining his job are primarily dependent upon his own efforts. But all the workers together often feel—rightly or wrongly—that by their behavior they can stretch out the work to be done and prolong the average period of employment of the whole group. In order to make jobs last they will consciously or unconsciously slow down their efforts—with detrimental effects upon productivity, costs, and profits. And such is the group solidarity of any set of men working in close contact that even those workers with high seniority and no fear of unemployment will actively and passively pursue these same tactics; for just as young workers look forward to the time when they will have gained seniority and act accordingly, so too do the old-timers remember back to the days when they were at the bottom of the ladder. Besides, rarely does one have so much seniority but that he is outranked by someone else, and even his job may be thrown in jeopardy whenever there is a really deep falling off in business activity. Given the above set-up, increasing the worker's feeling of security by means of guaranteed wage plans may contribute to an increase in labor productivity.

This completes our brief survey of the ways i which the economic burden of unemployment ten to fall with heavy weight upon the workers through (1) reduced earnings, (2) loss of oppor tunity for useful and satisfying activity, wit attendant costs to the community at large, (3 through variability of the receipt and expenditur of income, and (4) through a widespread feelin of insecurity and tension among both those em ployed and those unemployed.

We turn now to an examination of the burde experienced by the employing industry.

---

[11] It is not at all paradoxical that even recently hired workers tend to favor seniority rules. They hope to possess seniority themselves some day.

THE COST OF INSTABILITY TO INDUSTRY

The burden of unemployment falling on the workers is only part of the total story. Heavy unemployment causes national income to fall sharply. During such times industry is operating at low capacity levels. The rewards to property decline.

Historically, there seems to have been a rather remarkable constancy in the proportionate division of the total national income between personal effort (wages, salaries, and personally earned entrepreneurial profits) and property income (interest, net rents, and profits combined). It appears that the burden of heavy unemployment tends to be parceled out in something like the same proportion between property and labor income.

If we take property income as a whole, probably similar conclusions can be drawn in the case of easonal and other noncyclical idleness. If these rregularities cause an annual loss of national in-ome and product of some billions of dollars, an ppreciable fraction takes the form of lower earn-ng returns to property income receivers. Success n a thorough-going stabilization program would ean more stable and probably higher profits over e cycle as well as higher wages. Therefore, oth labor and management have a mutual stake ironing out irregularities in production and nployment.

We have seen that the average take-home pay nds to be decreased by instability of employment different industries. What may we infer about e profit rate in industries which are subject to e greatest fluctuations in activity? Can we ex-ct that the effective maintenance of guaranteed ges would be at the expense of the profits now rned by variable industries?

To the extent that any wage or job guarantee duces, accompanies, or follows upon successful bilization of production, the second question swers itself. If steady production at a high el tends to increase labor efficiency and to reduce pensive turn-over, the program may much more n pay for itself. But if we must assume that ranteed wage income is maintained in indus-es that are still subject to irregularities of de-nd and production, the answer to the question whether the burden will fall on profits is not simple. It depends in part upon the answer to the first question as to how profit rates have in the past accommodated themselves to differing degrees of instability.

If we select those industries with the greatest cyclical or seasonal fluctuations and compare their profit rates with steadier industries, there does not appear to be any strong relationship between profits and instability. For the period 1935–39, which includes a recession as well as years of expansion, the average profit rate of 10.1 percent for all durable goods hardly differs from the 9.8 percent for all nondurable goods. Automobiles, one of the most strongly cyclical and seasonal industries, has among the highest rates of profit, whereas iron and steel, also a cyclical industry, has rather low profit rates.[12]

If industries which had previously been stable were suddenly to become cyclically or seasonally irregular, then profits would immediately be affected adversely. Something like this probably happened as a result of the unexpectedly deep depression of 1929–33, profits in many lines being very hard hit. But by and large, unstable industries have a history of being unstable. When capital chooses between going into the canning industry and some other line, it does so with the expectation that supplies and operations will there be bunched into a relatively few months of the year. Similarly, an industry like baking is expected to be fairly stable, both seasonally and cyclically.

To the extent that these expectations are correct—and they certainly are not necessarily so—there is a tendency for profit rates to be equalized (over the cycle and year) by the competitive movement of capital between and among industries. That being the case, the residue of the economic burden of idleness that is not thrown upon the workers in the given industry—this residue is not borne by the industry's capital. Instead it is shifted forward and backward to workers and investors elsewhere.

In overcrowded lines of activity where rivalry is very keen and profits are chronically low, the cost of even customarily expected fluctuations in production may not be allowed for in price setting. Many of our industries with the greatest amplitude of seasonal fluctuation happen to meet this description at least in part. However, for the most part, the low profits experienced in these fields ought properly to be kept analytically separate from the fact of seasonality of operations. Were the same total level of demand to be spread evenly over the year or cycle, while at the same time the conditions of over-entry into the industry and past excessive investment were yet to prevail, we might still expect profits to be low. A real exception to this statement is provided by the case in which people are encouraged to overinvest their capital in an industry because of the appearance of high profits during the short-lived busy season. This would be the counterpart of a similar possibility in the labor field, where workers overcrowd an industry because of short-sighted concentration upon the transitory high hourly rates to be earned for a few months of the year or a few years of the cycle.

---

[12] Unpublished study of Office of Price Administration, entitled "Return on Net Worth, Before and After Taxes, 1936–44, 2,500 Leading Industrial Corporations."

Other fields are to be found such as durable consumer goods and chain department stores where operations show a distinct seasonal and cyclical pattern but where profits are nonetheless fairly high. In many markets one or a few firms occupy a strategic position of dominance by virtue of efficiency of operation, advertising, research, trade marks, patents, and so forth. New firms are not able to come in and compete away the monopoly or quasi-monopoly returns of these concerns.

From the analysis of the last section, a few tentative hypotheses may be drawn as to the possible effect of introducing guaranteed wages upon the profit position of unstable industries. Depending upon the variability of the industry and upon the limitations placed upon the guarantee, we could expect profits to fall in the short run after the plans are first put into effect—unless indeed the plans induced an increase in efficiency. In the longer run, and to the extent that capital can be made mobile, capacity and output would gradually shrink in the more variable industries.

More and more the burden would then be shifted forward to the consumer through higher prices, or backward upon wage rates in general—not through actual pay cuts, perhaps, but through a slowing up of the rate of increase of real wage rates. Part of the burden might well fall upon monopoly profits. In fact the cut might be covered by increased efficiency.

Nevertheless the case should not be overstated. Even if profit rates were equalized over all industries in the long run, we could not conclude that profits would necessarily escape all the burden of the extra costs entailed by guaranteed wages. True, the rate of profit in the particular unstable industries would be relatively unaffected. This does not preclude the very real possibility that the "equilibrium rate of profit" would be lower under a regime of over-all guaranteed wages than under the present form of the wage contract where labor can be made a variable monetary cost. There is no reason why the historical proportion between labor and property income would necessarily be preserved in the face of so drastic an institutional change. In technical terms, the "imputed net productivity" of capital depends very much upon wage rates, collective bargaining, labor "productivity," taxation and other cost conditions. Under guaranteed wages, we cannot tell with certainty whether equilibrium profit rates would rise or fall. Any possible effects upon profits would have further repercussions on consumption, saving, and investment propensities, as we shall see in chapter IV of this report.

Probably, as we have seen, workers now directly bear the major cost of instability. Also, it is clear that the portion which workers do not bear may in part be shifted off the shoulders of the employers directly concerned to consumers and to industry in general. But still there remains some element of cost to the industry directly involved Is it not to the selfish advantage of the industry itself to regularize its activities by means of sta bilization programs? The answer is—to some de gree—yes. Doubtless industry is already pursu ing many such policies; the observed degree of ir regularity of operations in our economy is b no means the maximum conceivable.

Doubtless, too, much more remains to be dor in this connection. Business management is fa from omniscient. Custom, ignorance, and inert play a role in preventing companies from active undertaking policies which are to their own max mum long-run profit advantage. Often compani are not fully aware even of their own irregul pattern of operations; many devote far less atte tion to stabilization programs than to other pects of sales promotion, product development a research, quality control, and cost accounting. The pressure of management groups such as the American Management Association, the Chamber of Commerce, and the Committee for Economic Development, and the pressure of organized workers through collective bargaining, and of government nd the public-at-large, is all to the good in spur- ring corporations on to studying the problem of further stabilization programs. Engineering and fficiency studies have time and again shown that he surface is as yet hardly scratched. When every orporation of any size has a major executive and izeable staff working creatively upon this prob- em—then and only then can we expect even the elf-interest of the corporation, to say nothing of he economy at large, to be well served.

We can expect that the obvious stabilization olicies, which hold out immediate economies with ttle cost and no risks, have already been exhausted large part. What is needed is for management display with respect to thorough-going stabili- tion efforts the same venturesomeness and im- gination that it displays in promoting a new prod- t or in risking the construction of a new plant.

And yet, despite the above exhortation, there are od reasons to believe that under present com- ercial and financial institutional set-ups, the rd-boiled single enterprise has only a limited otive to pursue extensive stabilization policies. uring the last 25 years, good will, effort, initia- e, and intelligence have been applied again and ain to the problem. Yet plan after plan for untary stabilization has petered out or become asualty of business depression. With a loose or market and wages a variable cost, irregular duction is not always expensive production.

his condition may not last. While it would tainly be premature to conclude that the busi- s cycle is a thing of the past, nevertheless, both lic and private enterprise have learned much; today there is widespread recognition and de- nination that we must do everything in our er to prevent such catastrophic declines in onal income and production as characterized slump which followed 1929.

n any event, the longer that high employment litions are maintained, the greater will be the immediate dollar-and-cents incentive to regularize any remaining instability of productive activities. Depression conditions in the labor market have left corporations with a heritage of personnel policies, which however appropriate they may have been in the years of labor surplus before the war, may prove extremely costly in a high-employment economy.

Let us take the automobile industry as a case in point. Suppose manufacturers bow down to the seasonal character of auto demand once the immediate postwar backlog of demand has been partially filled, and in consequence are able to provide only some 8 months' work to the average employee. What will the result be? Will workers be compelled to lay off for 4 months, living on unemployment-insurance benefits and previous savings, and borrowing, or on relief? Probably not, if jobs are really plentiful. Then, when auto production is again resumed, many will be called but few will answer. Large numbers of workers will have been attracted by job offers with other concerns. Any firm with unstable employment would have to raise wage rates and undertake costly recruitment policies to keep a suitable labor force.

During depressions the cost of labor turn-over to an employer consists primarily of the costs to be incurred in securing and training a new worker. In modern mechanized industry, where a premium is placed upon general intelligence, manual dexterity, and basic training in the use of nonspecialized machinery, it is not at all impossible that the expense of training new workers is a good deal less than would appear from many exaggerated accounts. After not many weeks, a worker transfered to a new department or hired for the first time, may be nearly as efficient as he is ever likely to be; especially since the novelty of a job often elicits an enthusiasm and zeal which wears off with continued experience. Possibly this explains why the alleged reduction of cost of labor turn-over has been so ineffective in the past as a spur to stabilization. But in a full-employment economy, every employer will be pitted against every other employer in an effort to secure more labor in a tight market. Labor laid off may be lost forever. From any one firm's viewpoint, labor separations then tend to give rise to labor shortages rather than simply to labor turn-over.

This leads us to stress once more that production stabilization and the guaranteed wage involve much more than business cycle unemployment. The following chapters undertake to show the relationship between guaranteed wages and other programs; also, the direct relationship to the over-all level of aggregate demand and unemployment, and to the efficient use of resources in a high-employment economy.

III. THE GUARANTEED WAGE IN A BROAD SECURITY PROGRAM

Substantial security of income or employment, or both, is everywhere more and more recognized as a primary goal of modern democratic societies. This goal cannot be achieved by any one method. In all modern societies many institutional arrangements, programs, and procedures have been adopted, designed to contribute to stability of income or employment. Among the most important of these are (a) a variety of social security measures and (b) various programs to stabilize employment in the individual firm and for the economy as a whole.

DIFFERENT PATTERNS OF JOB SECURITY

Employment contracts under modern conditions typically are terminable without notice or upon so short notice as to give virtually no security of tenure. Nevertheless a substantial proportion of modern workers feel fairly secure in their jobs. In many cases it may be assumed that employees of long standing regard their positions as more or less permanent. Such employees are not likely to fear dismissal for cause. In general, they are not likely to be greatly concerned about lay-offs, except in the case of wholly unforeseen catastrophes of a character which are not regarded as very probable. It appears true that human beings are prone to be unduly optimistic and to underestimate risks of a character which they are not in the habit of facing more or less continuously. By and large, employees of long standing probably experience a feeling of security greater than is in fact justified by the course of events.

Employees who feel a sense of security in their job by reason of long tenure are likely to underestimate the importance of unemployment insurance, and related measures, as means of ensuring some degree of income security. For these employees it is security and continuity of the job already held that is really important, not the easing of transition to a new job.

But a large proportion of employees are not in this favored position. Typically their tenure of employment with any one firm is relatively brief. For many workers, a job is, even at best, a comparatively temporary thing. Lay-off or voluntary separation is a continually recurring experience. Workers who are accustomed to only short-period job tenure doubtless fall into different categories with respect to reemployment experience. Some, by reason of the character of their occupation, adaptability, resourcefulness, etc., expect easily and quickly to find new employment. In the transition to a new job, unemployment insurance plays an important role.

In bad times, however, reemployment, even for the alert worker, becomes difficult if not impossible. Unemployment insurance becomes then ar important means of support, just as it is for thos workers who encounter difficulty at any time i finding new work. It provides, however, only fraction (usually 50 to 60 percent) of normal earnings, with maximum limits ranging from $13 t $28 per week; while the maximum duration o benefits runs for only 14 to 26 weeks. It can serv as an important stop-gap for seasonal and trans tional unemployment under conditions in whic opportunities for reemployment are reasonab good—that is, in a relatively buoyant labor mark where aggregate demand is on a fairly satisfacto level. In addition, the dismissal wage can help bridge the gap in the event of technological unemployment, consolidation of firms, or a secular c cline in a firm's business.

A considerable proportion of the Americ labor force, even though at times laid off, does t typically change jobs. Such workers regard themselves as "attached to a firm" even thouh they experience frequent and fairly long perids of unemployment. Thus, in the automobile ndustry in the period of 1935–39, workers were employed on the average for only about 75 percent of full time.[13]

The table below gives a quantitative picture of the number of workers of different years' service with a large public utility system. In 1929, when jobs were plentiful, the turn-over of workers was very high. Consequently, the percentage of vorkers with less than 1, 2, or 5 years of service vas relatively high. During the depression, the icture was changed greatly. Few workers had een recently hired, and the number "separating" rom the company was relatively small. Workers vith 5 years' service began to be the rule rather han the exception, so that even workers with high eniority rating would have faced lay-offs if furher widespread contraction of operations had ecome necessary.

ercent of workers with varying lengths of service in a large utility system

Year	Percent of workers			Number of separations as a percent of average number of workers
	With 1 year or less	With 2 years or less	With 5 years or less	
29	25	38	61	31
32	1	2	33	10
36	9	12	17	7
38	2	10	22	7½
1	19	26	36	12

In strongly organized industries, workers are s vulnerable than formerly to dismissal, or disrge "for cause." So long as times are good, on workers with seniority are also protected m lay-offs in a wide variety of industries where traction of output is a gradual affair involving y the more recently acquired workers. There other industries, however, where technology ires whole plants and units to be shut down n output is contracted. In such industries, strong union organizations cannot protect kers with high seniority rating from being intermittently laid off—even in years of fairly high business activity.

The demand for a guaranteed wage is likely to be strong in industries of this type. Such workers, to be sure, not infrequently take advantage of unemployment insurance and job opportunities offered elsewhere in the interim period of temporary unemployment. Yet a large proportion more or less regularly experience temporary unemployment each year, and await a return to their old job without obtaining, in the interim, work elsewhere. To repeat, it is particularly for workers of this character that the guaranteed wage plan makes a strong appeal. These workers are, in a sense, "attached to a firm," yet the number of days worked per year is low. The conditions of the industry prevent or make difficult a high ratio of days worked to working days in the year. If the firm could diversify its production so as to dovetail employment throughout the year, a high ratio of days worked to working days could be achieved. In view of the character of the modern labor contract, it is probable that most employers have not yet seriously tackled the job of giving steady employment to workers regularly attached to their firms. If the labor contract were on the guaranteed basis, these firms would be compelled to explore to the utmost ways and means of finding steady work for those "attached to their firm."

GUARANTEED WAGES AND STABILIZED EMPLOYMENT

Where unemployment is primarily a matter of seasonal fluctuations, and other types of work interruptions of a short-term character, the guaranteed wage plan seems to be peculiarly suitable as a device to help solve the problem of job security. If under such conditions the guaranteed wage became the rule for all competitors in an industry, more and more those competitors would survive who proved most resourceful in the development of stable, year-round employment. At first, doubtless, relatively little progress would be made and the guaranteed wage might prove to be a heavy burden on the industry. This might involve a rather drastic readjustment of prices or wage rates or both. Eventually, however, as more and more firms increasingly solved the problem, costs would be reduced. Accordingly prices could be lowered

---

he average weekly hours of automobile workers for the -39 period, using Bureau of Labor Statistics data weighted e Bureau's employment indexes, were 36.1. These were the ge weekly hours for employees working. Total labor force stimated from numbers of employees reported to the Fedureau of Old-Age and Survivors Insurance, with a correcor inclusion of nonproduction workers. The automobile force appears to have averaged about 18 percent more than erage force at work, so that average weekly hours for the force averaged about 30.6.

again or wage rates raised, or both. The net social gain would be steady year-round employment for the workers and an enlarged real income for the community as a whole.

A LIMITED GUARANTEED WAGE

In what has been said above, the assumption is made that the guaranteed wage would be applied to all, or nearly all, the workers employed by the firm. But even firms with short-run irregularities in employment have a certain residue of workers who are continuously employed. If the concept of the guaranteed wage were applied only to these workers, the plan would become at once more feasible, but also would accomplish relatively little. Similarly, with respect to industries afflicted with cyclical unemployment, a guaranteed wage which involved only that residue of workers which a firm can reasonably expect to hold through even a deep and prolonged depression, would become highly practical, but correspondingly also of less value.

Nevertheless, even this limited concept deserves consideration. It would indeed not solve the problem of either income or job security. These difficult goals must be attacked from a great many angles. The guaranteed wage is only one among many approaches to the problem. Indeed, if too much were attempted by this method, other more promising methods might be seriously impaired. The guaranteed wage, we believe, does have its place as a part of a larger program. Even the minimum concept of the guaranteed wage referred to above could achieve something of substantial value. If each firm gave assured employment to that fraction of its peak employment which experience indicates to be feasible and practical, a formally recognized status of security might be given to an appreciable fraction of the entire labor force. This would, at any rate, be something to start with. The problem would then be sharply posed: if such a fraction of workers were protected under the guaranteed wage status, what could then be done (1) to provide in other ways (dismissal wages, unemployment insurance and over-all stabilization policies) as much security as is possible for the uncovered employees, and (2) to expand gradually the number coming under the guaranteed wage plan.

THREE ROADS TO JOB AND INCOME SECURITY

Comparison may usefully be made between (1) the guaranteed wage plan, (2) unemployment insurance, and (3) a full employment program. In making this comparison it will be helpful to assume that each measure is a part of a general pattern in which each reinforces and supplements the others as means to provide security for workers. Thus considered, what can each of these three approaches contribute to the problem of security?

The full employment program aims to provide security by ensuring a good market for labor services. The goal is adequate aggregate demand, so that workers can readily find and obtain jobs. This plan does not guarantee a job to any individual. It provides a favorable market in which he may seek a job. The mere fact that the aggregate demand for goods and services is sufficiently high to ensure a good market for labor services, will not prevent fluctuations in employment in seasonal industries. It will not prevent shifts taking place between industries and between regions. A man living in town X may not be able to get a job in his particular skilled occupation in town X; or anywhere if his skill has become obsolete, or his demands exorbitant. Aggregate over-all demand does mean, however, tha job opportunities are in general plentiful throughout the Nation. A man cannot sit on his fro porch and expect just the job he wants to come t him. But if he is alert and active, the market favorable. Labor is in good demand througho the country. There are many job opportuniti from which one may choose. And retraining programs, employment offices, travel allowances, and adequate housing facilities (essential parts of complete full employment program) should make the task of transfer to new jobs and other regions relatively easy.

Such in brief is the goal or function of a full employment plan for job security. It does not guarantee a job, and at best there will be unemployment. In particular there will be seasonal, technological, and transitional unemployment. The plan thus falls short of adequately meeting the problem of security. Something more is needed.

The unemployment insurance program aims primarily at a minimum of income security, and does not directly attack the problem of job security. The program assumes that workers will become unemployed for all sorts of reasons—seasonal fluctuations, fluctuations in the business cycle, changes in technology which throw people out of work, structural changes which adversely affect certain regions, shifts in population, foreign competition, etc. The program is not designed directly to remove any of these causes of unemployment. It is designed merely to ensure a temporary minimum income to workers who are out of a job. As a by-product, the program does indeed, it is now beieved by most economists, make some contribution (if properly financed) toward the maintenance of ggregate demand. But at best its contribution o the maintenance of purchasing power is relaively limited, and its main function is to provide minimum income to those out of work. To reeat, the program is designed to give minimum inome security, not job security. The income reeived is not paid in return for work. The payent is made basically in accordance with the rinciple of partial income maintenance,[14] not in ccordance with the principle of productivity.

If now we extended unemployment insurance ndustry or firm financed) far beyond the limits hich are now actually applied in practice to the oint of full coverage of wage income for the eriod of a year or perhaps a minimum of 40 eeks of the year, instead of only 50 or 60 percent wages for 14 to 26 weeks, we should have arved, at least in terms of the income receipts of e protected individuals, at the same point as e guaranteed annual wage. Under the guarand wage, of course, the worker not only receives ontinuous income payment during the period which the wage is guaranteed; he may also be ject to the call of the employer for the performe of work.

rom one point of view the guaranteed wage be looked upon as 100 percent unemployment urance, for at least a limited time. But it is en more than that, especially where it involves "guaranteed work" as well as income. It carries the principle of merit (or experience) rating to its ultimate degree; the whole burden of maintaining the worker is assumed by the employer. Any use he can make of the workers is all to the good since his labor costs go on anyway. Under the unemployment insurance plan, the worker is obligated, in return for income payments, merely to register at the public employment office and actively to seek work if it is available. If work is found, the insurance payments cease and wage payments begin. Under the guaranteed wage, wage payments continue with or without work. but the worker is under obligation to work whenever the employer so directs. And especially if the guaranteed wage is integrated with unemployment insurance, as we suggest, he will also be under obligation to seek work elsewhere.

The guaranteed wage plan, accordingly, as opposed to the principle of unemployment insurance, tends in the direction of bringing work to the worker in the employer's establishment. Unemployment insurance, through the unemployment exchanges, seeks, on the other hand, to send the worker to the job wherever it may be. This difference can, however, easily be exaggerated since an employer under the guaranteed wage also may seek to place his idle employees in jobs elsewhere and with other establishments.[15]

Nevertheless, the guaranteed wage tends rather more than unemployment insurance toward fixity of jobs in regions and establishments to which work must be brought. The maintenance of labor mobility is no easy matter; yet much could be done to keep productive resources fluid in reference to changes in technology and in demand. Employment offices, operated in conjunction with unemployment insurance, if effectively managed, aim to promote the movement of workers from old establishments and regions to new ones as dynamic changes in products and in wants arise. Under the guaranteed wage plan the main effort is to provide work for the worker on his old job or at least in the firm to which he is attached; under unemployment insurance the emphasis is placed upon connecting up workers and jobs in any firm offering suitable work, preferably in the

---

A rough calculation suggests that unemployment compensacovers less than a fifth, and possibly not much over a tenth, e wage loss from all unemployment. The system is much effective in compensating total unemployment wage loss in times than in bad.

[15] See our policy recommendation in chapter VI calling for an integration of unemployment insurance benefits and guaranteed wages.

region where the worker is located, but if not there then elsewhere, at least within reasonable limits.

To sum up, a full employment program is designed to maintain, within reasonable limits, adequate aggregate demand. Emphatically, it will not guarantee every worker a continuous job. It does no more than to ensure plentiful employment opportunities—a brisk demand for labor. And in order to achieve reasonably full and sustained employment, a fairly high degree of labor mobility is required. A full employment program must therefore include, as a part of the plan, retraining provisions, travel allowances, and adequate provision for working-class houses where jobs are available.

Nevertheless, at best, there will still be seasonal, technological, and transitional unemployment. A full employment program, therefore, leaves many workers unprotected unless supplemented by a well-developed scheme of unemployment insurance. Social security is therefore necessary, in order that at least a minimum income will be received by those workers who suffer the effects of the unavoidable unemployment which is a by-product of the manner in which production is carried on under modern conditions. This insurance of a minimum of income, since a job cannot continuously be guaranteed to everyone, is the right of all workers, and is so recognized in all modern democracies.

Within the framework of a full employment program, supplemented by unemployment insurance, a highly important function can be served by the guaranteed wage. There are already a substantial number of persons, including professional and salaried workers and some wage-earners, who have achieved a fair degree of job security, if not in a formal guaranteed wage, at least in its practical equivalent. This group could doubtless be enlarged even without a full employment program. Standing alone, however, without the protecting influence of a steady, brisk demand for labor, any widespread expansion of unlimited guaranteed wages might encounter serious difficulties. Within the pattern of a realizable high employment program of sustained aggregate demand, the guaranteed wage could be extended to include a fairly high proportion of workers in the labor force. For some firms or industries the number of weeks guaranteed might be 40, for others 45, and for others 50. The guaranteed wage, safeguarded in view of the risks involved and properly integrated with unemployment insurance,[16] could play a significant role as a means of providing income security. Most important of all, however, is the task of securing continuing high levels of employment. Income security cannot take the place of steady productive employment.

IV. GUARANTEED WAGES, OVER-ALL EFFECTIVE DEMAND, AND THE BUSINESS CYCLE

INTRODUCTION AND BRIEF SUMMARY

The subject matter of this chapter, the quantitative effects of guaranteed wages upon total demand and upon business cycle fluctuations, is intrinsically complex and can only be analyzed in rather technical terms. Perhaps it is for this reason that the voluminous literature on guaranteed wages scarcely scratches its surface. Nevertheless, no economic analysis of guaranteed wages could be complete without coming to grips with the question as to how effective such plans can be in reducing over-all unemployment and in moderating the business cycle.

For readers who are not interested in the technicalities of analysis, a few of our more important findings may be briefly sketched. However, to appraise their validity, there is no escape from the more detailed analysis which follows this section

In this chapter we do not consider governmenta programs of any kind. If the guaranteed wag were to be a governmentally financed program that would be one thing; and the economic an political implications of such a plan would the need to be examined. But this is not our concer in this chapter. We consider here the economic of a privately financed guaranteed wage. Ho would a privately financed guaranteed wage, take by itself, affect (*a*) the fluctuations of the busine cycle, and (*b*) the level of effective demand, pr duction and employment over the cycle. It is i portant, we repeat, for the reader to rememb that the problem before us is concerned exclusively with the economic effects of a privately financed guaranteed wage.

---

[16] The problem of integration is discussed in ch. VI.

Those who concentrate upon the expansionary effects of guaranteed wage payments, to the neglect of how these payments are financed, come out with an exaggerated notion of the efficacy of wage guarantees to combat depression and unemployment.

It is not inconceivable that the guaranteed wage could be the means of inducing (by providing worker security and in other ways) a higher man-hour productivity. But there is no evidence from experience that increases in productivity, as such, tend to iron out the cycle or to raise the level of employment over the cycle. Increases in productivity are important from the standpoint of raising the standard of living, but not from the standpoint of eliminating the cycle. Guaranteed wage payments (whether they induce increased productivity or not) may, however, help to iron out the cycle if they are financed from reserves accumulated in good years and paid out in bad years; or they may, to some extent, raise the level of employment in the depression phase, through the redistribution of income when financed on a pay-as-you-go basis.

The fact that a guaranteed wage plan might more or less "pay for itself" is certainly signifiant. But only insofar as the plan redistributes ncome over time, or else redistributes income beween economic groups, will it have any effect ither on the stabilization of employment or in aising the level of employment. Our tentative onclusion is that the guaranteed wage, by itself, s not likely to prove very effective either as a eans of stabilizing the cycle or of lifting the level f employment over the cycle, although the guarnteed wage may be partially effective in regularing seasonal employment.

With respect to the redistribution of income, obody can say just what percentage of the finanal costs of guaranteed-wage plans will fall on rporate stockholders rather than on consumers wage earners. Except to the extent that the sts fall upon net corporate savings (without fecting dividends or interest outlay, or net corrate outlays on plant, equipment, or invenries), guaranteed wages may be regarded as a rm of personal income redistribution. Such a redistribution may be highly desirable on social grounds. But the available statistical data showing (*a*) how people in different income classes allocate their extra dollars between saving and consumption expenditure, and (*b*) the relatively small proportion of the total national income flowing to the high-income groups, suggest that such redistributions are of somewhat limited quantitative significance in raising the level of over-all purchasing power.

Apart from such personal redistribution and its relatively limited effect, we conclude that in periods when net investment outlays for the economy as a whole are deficient, causing a decline in employment and in business profits, the guaranteed wage may, indeed, for a time maintain consumption expenditure. For this to be true in these circumstances, the payments would have to be financed from accumulated business reserves previously set aside to cover guaranteed-wage payments in the subsequent depression, or else from current undistributed profits and depreciation charges not invested in plant, equipment, or inventories. Under the assumptions made (apart from redistribution of personal income via lower wages or higher prices), these would be the only methods of finance, government support being ruled out. But the amount of guaranteed wages that could be financed from depression business profits and surplus would be quite limited, even though no account were taken of possible unfavorable effects on the economy which such losses might entail. And if the amounts set aside in reserves in boom years are large enough to cover the risk involved, new problems are encountered which are rather serious. While moderate reserve accumulations could help to iron out the cycle, large reserves (as we shall see in the discussion which follows) might seriously intensify the savings-investment problem. Thus, either way, there are, we believe, rather severe limits to the extent to which the guaranteed wage can iron out the cycle or raise the general level of employment over the cycle.

We do not wish to overstate or overemphasize these somewhat pessimistic conclusions. Indeed, in the discussion that follows they are qualified at many points. Nonetheless, we must once again stress the limitations of the guaranteed wage as a remedy for the business cycle, and emphasize the need for a well-rounded full-employment program including both public and private policies designed to keep our economy stable at a high and growing level of real income.

JOBS AND MARKETS

Let us begin our detailed technical analysis by considering the simple view that guaranteed wages and employment maintain incomes and jobs, that steady incomes mean steady sales of business, which in turn give rise to high and steady employment. In short, jobs make markets, markets make jobs, and so forth, indefinitely. According to this view, a serious depression like that of the early thirties is nothing but a vicious circle; for one reason or another, the public and business has become frightened enough to contract spending; this initial contraction of spending has resulted in reduced levels of business sales and consumers' incomes; and this situation tends to perpetuate itself at low levels of national income and high levels of unemployment.

Some such theory as this is widely held both by many conservatives and many liberals. The latter say, "All we have to do to cure such a situation is to prime the pump for a little while. Once the system gets back on its feet the Government pump priming can stop because the new circular flow of income-sales will be able to maintain itself at high levels of employment."

We believe it fair to say that the majority of modern economic experts reject this view just as they reject its oversimple conservative version which goes something like the following: "Any depression can be temporary if businessmen and the public will keep their heads and realize that prosperity is just around the corner. The Government should steer clear of the whole situation, except for a little necessary emergency action. Then, if people will only act upon the assumption that conditions are fundamentally all right, and if they will only 'buy now' instead of later, the corner of prosperity can be permanently turned."

The majority of modern economists, let us repeat, do not believe that such a theory squares with the monetary, statistical, and historical evidence accumulated by students of the business cycle. They find themselves forced to reject the assumption that, like Gilbert and Sullivan's all-powerful Mikado(all we have to do is declare jobs guaranteed, and ordering that this be done is just as good as if it were done.

We do not deny that there is a germ of truth in the above viewpoint: Pessimism and reductions in spending do involve some elements of the vicious circle character, and the descent into a depression is of a cumulative, self-aggravating nature. But fundamental facts of economic life are ignored by this overly simplified theory. The fact is that people do not spend all their income on consumption goods and services. Retail sales by business to the public constitute only a part of the total national income produced at high levels of employment. Around one-eighth of national income,[17] when employment is high, has throughout our history of the last half century gone into the form of investment goods or net capital formation. And it is capital formation that basically represents the difference between prosperity and depression. All the available statistical evidence shows conclusively that capital goods and durable consumer goods experience the greatest amplitude of variation over the business cycle. Moreover, this variation spreads throughout the economy, in particular affecting the volume of nondurable consumption expenditures and replacement capital expenditures, and so it has a magnified effect on aggregate outlays, income and employment.

For the purpose of this report, it is not necessary to enter upon the controversy as to just what the long-run prospects for investment are, or just what in the past have been the primary causes of investment fluctuations. It is enough to record the fairly substantial agreement of economists that among the important factors affecting investment behavior are scientific inventions, technological innovations, population movements and growth; changes in tastes; relations between different elements in the price, cost and wage structure; interest rates and availability of capital; investor psychology and businessmen's expectations; attitude, legislative acts and policies o government; governmental public works and public development projects; and so forth.

Now it is not at all clear how much, if at al the guaranteeing of wages as such would affec the sum total of these factors in a manner favorable to the maintenance of the high levels of total outlays necessary for full employment—if, without guaranteed wages, otherwise adequate demand were inadequate. It is not even as yet clear in what direction or to what degree the over-all balance of saving and investment would be affected by the widespread adoption of the guaranteed wage.

---

[17] If one preferred to relate gross investment to gross nation product, the ratio of investment to national product would far higher.

WILL GUARANTEED WAGES STABILIZE CONSUMPTION?

But cannot the following limited case be made for guaranteed wages: Would not the widespread doption of such plans at least succeed in stabiliz- ng consumption, with the effect that fluctuations n national income would then be confined to the elatively small sector of the economy—the cap- tal-goods industries? Also, would not the suc- essful maintenance of consumption moderate, at east in the short run, some of the wide swings f investment—those dependent upon the level of rrent business sales? Finally, would guaranteed ages raise the total level of consumption over e cycle, and so also lift the average level of vestment?

These are separate but related questions. The swer to the first is fundamental and prepares e way to an answer to the others. If it can be own that guaranteed wages would stabilize the vel of consumption, much (though far from ough) will indeed have been proved. For under e present system of wage and job tenure, fluctua- ns in the relatively minor (say, one-eighth) part our economy concerned with net investment give e to "multiplied and amplified" fluctuations in sumption as well. Thus if full employment national income in the postwar were about 0 billion, and net investment were to drop y to nothing, the loss to the economy would simply be around one-eighth of national in- e—or some $20 odd billion.[18] As workers and perty-owners in the capital-goods industries income and contracted their consumption expenditure, there would be set in motion a chain of cumulative contractions in income which might be two or three times as large as the initial decline in investment expenditures. In short, a relatively small failure in investment outlay tends to result, under our present system, in considerably larger changes in total income, because of the "secondary" contraction of jobs and consumption expenditure.

If the consumption outlays could smoothly and instantly rise whenever investment declines, we should not experience any general decline in aggregate demand in a prolonged depression. But this is simply not possible. Individuals will not suddenly change long-established customs and habits with respect to the disposition of their incomes between consumption and saving merely because, from the social standpoint, the turn in the cycle calls for an increase in spending out of a reduced income. Thus an offsetting increase in consumption cannot and does not occur. Worse than that, consumption actually falls off when investment declines, since unemployment and declining business prospects induce a decline in private spending patterns.

This induced decline in consumption could indeed be avoided if, by some "magic," substitute income payments could be found to take the place of the declining capital-goods pay rolls. These substitute income payments, since they do not correspond to any productive output, would be in the nature of "transfer" payments. Ideally, they might be financed out of the stream of saving which always characterizes full-employment income levels. By this "magical operation" the income flow would be maintained even though net investment should fall to zero and cause considerable primary unemployment. In short, the savings stream, instead of financing new investment, would be transferred to idle workers and the owners of idle resources. Total consumption would thereby be maintained.

Perhaps a bald statement of the problem in these terms may help to reveal the lack of realism involved in over-simplified assumptions with respect to the maintenance of consumption and employment. Unfortunately, economic analysis of guaranteed wages does not seem to substantiate the claim that this device would, as a first approximation, necessarily tend to maintain consumption for

---

Even when gross investment is positive in the sense that capital goods are being produced, net investment may well egative if the total value of capital goods output is less than mount of capital goods being used up. In view of the fact gross and net investment differ only by the fairly constant itude of capital consumption or depreciation, absolute es in gross and net investment can be used interchangeably urposes of business cycle analysis.

any appreciable period of time at the appropriate full employment levels, i. e., roughly at seven-eighths[19] of the full-employment level of net national income.

To illustrate the point, let us consider the case where investment opportunities are only such as to replace existing capital. It is not enough then for all employers in the consumption goods industries to undertake guaranteed wage plans. Rather, all employers—in both consumption and capital-goods industries—must carry through with such guarantees. Total consumption and saving typically depends upon total national income (at least as a first approximation) in such a way that in order to ensure a volume of consumption equal to seven-eighths of full employment national income, the actual amount of national income accruing to people must be eight-eighths of the full employment level. If investment opportunities are for the moment moribund, where is the "missing eighth" to come from?[20]

If investment opportunities are temporarily in large part saturated—plant and equipment having been built up during the preceding boom period to about as far as prevailing technology justifies, and if houses, hotels, office and commercial buildings have been constructed to the extent (and in fact often farther than is) justified by growth and the requirements of prevailing standards—then investment outlays will decline even though consumption expenditures could, in some manner, be stabilized at the boom level. And, if this is so—and the experience of business cycles for 75 years supports this analysis—then the producers of capital goods will not be able to continue to operate at levels adequate to maintain their pay rolls or to pay guaranteed wages to their employees. And when the market for the capital-goods industries drops out, then a large fraction of the market for consumers goods will also disappear. This is the situation which cannot be waived by the over-simplified theory which holds that jobs provide pay rolls, pay rolls provide markets, and markets in turn provide jobs. The overly simplified version did indeed fit reasonably well into a primitive economy where capital goods played no significant role. And it is for this reason, basically, that primitive economies, while poor, nonetheless rarely suffer from unemployment.

If the "missing eighth" continues to be lacking, how can consumer outlay be kept up to the maximum level reached in the boom? This is the crucial question: by what method of financing is the wage guarantee to be maintained? And yet throughout most of the literature on guaranteed wages, this whole problem is either neglected completely or passed over lightly. To remedy this defect, the rest of our chapter will analyze in some detail the effects of different methods of finance—pay-as-you-go and reserve.

If a guaranteed wage plan keeps a man from being laid off and makes possible the maintenance of his income, then it is not unreasonable to expect that it will result in an increase in his consumption purchases over what they would otherwise have been in the absence of such a plan. So far, so good—but we have not carried the analysis very far if we stop with the expansionary effect of guaranteed wage expenditure.

If the Government were paying the bill, not out of tax revenues, but by the printing of crisp new dollars or by loan-financing, that would be one thing. The discussion of the implication of such a policy, together with relevant comparisons with other antidepression programs (which might b more justifiable and promising), would take u very far afield and far beyond the scope of ou present study. When only private finance is in volved, it is necessary to give attention to som important factors which offset the favorable in come maintenance effects, as we shall see.

BUSINESS CYCLE STABILIZATION AN PRODUCTION EFFICIENCIES RESUL ING FROM GUARANTEED WAGES

Before entering upon a discussion of reser and pay-as-you-go financing, we must digress consider a point which is given considera weight in the literature of guaranteed wage pla Such programs, it is claimed, often more than p for themselves because of the production effici cies resulting from lower labor turn-over, grea labor efficiency, and fuller utilization of capital. Especially in connection with the ironing out of seasonal and irregular fluctuations is this likely to be the case. If the general business cycle is not brought under control, it is more doubtful that the increase in efficiency will be nearly as great as the costs of maintaining income payments in the face of conditions which fluctuate independently of the firm's control.

---

[19] This includes local community and other governmental services (education, for example) financed from personal taxes. In modern communities this is one important way in which consumers spend their incomes.

[20] All through this analysis we are assuming, it is to be remembered, that the guaranteed wage is financed by private industry and not by the Government. If consumption were automatically maintained by Government outlay, the case would be entirely different.

However, in any case there may be some savings in cost to offset against the expense of guaranteed wages. The question will inevitably be raised, therefore, as to whether widespread guaranteeing of wages cannot by itself iron out the business cycle, or at least maintain income steady throughout the cycle, and do this without any net cost to the business community. The remaining paragraphs in this section aim to throw light on these questions and clear the ground for the analysis of reserve and pay-as-you-go financing.

If the savings in cost through increase in efficiency were very important, the individual employer would be helped to finance his guaranteed wage, but it would not necessarily solve the problem of unemployment for the economy as a whole. ncreased labor productivity, meaning among ther things that less employment is provided by given volume of output, would raise the same roblems of unemployment and purchasing power s technological inventions. About this there is a rge literature, the consideration of which would ead us rather far beyond our immediate task. he mere reference to this literature is, however, ufficient to show that in the absence of a positive ull employment program, it cannot safely be assumed that technological and other developments esigned to increase worker productivity, would utomatically increase and stabilize aggregate employment and aggregate demand in the economy a whole.

If the guaranteed wage could induce an increase productivity sufficient to cover its cost, this ould be a great social gain leading, as with all vances in efficiency, to a potentially higher real come; and in an expanding economy in which chnologically displaced labor quickly became absorbed, this potential would actually be reald. But the mere fact that a guaranteed wage an or an invention "pays for itself," will not one tend to reduce the fluctuations of the cycle. There is no evidence from past experience (nor could it be expected on grounds of general analysis) that gains in productivity tend to have this effect.

Nevertheless, it is possible for the cost-savings of guaranteed wages to be used in such a way as to promote stability over the cycle—that is, by investing the financial cost-savings in good times into a reserve fund out of which payments are made in depression. This leads us into the whole problem of pay-as-you-go and reserve financing. After we have analyzed these devices, we shall return to efficiency cost-savings.[21]

TWO METHODS OF FINANCE

There are two methods by which widespread guaranteed wage plans could be privately financed. First, there might be some sort of reserve plan, according to which funds would be collected during the expansionist boom phase of the business cycle; and then during the contractionist depression phase of the cycle, these funds would be dispersed in the form of guaranteed wages. This same reserve principle is already in effect in connection with our Federal and State unemployment compensation program. The best case could be made for the anticyclical reserve method of financing if our economic system could be regarded as suffering only from cyclical swings above and below some "normal high-employment" level.

The second general method of financing guaranteed wages, is that of so-called pay-as-you-go. In contrast to the anticyclical reserve plan, in any given year the costs of guaranteed wages would be approximately balanced by current charges against sales or business gross income. Such a plan would involve relatively small payments in the boom years and therefore relatively small costs. In depression years, however, the payments would be large and the redistribution of current income would be considerable. The question to which we wish the answer is how much the payment of currently financed guaranteed wages might so redistribute income as to raise the level of consumption expenditures (or in more technical language the consumption function) and thus increase total aggregate outlay beyond what it otherwise would have been in the depression period. How would the cost be distributed between business net savings, wages, and consumer prices?

---

[21] See below, footnote 26, p. 445.

PAY-AS-YOU-GO FINANCE

Except for the earlier discussion of any possible induced increases in productivity, pay-as-you-go financing necessarily involves a process of redistribution of income between the various claimants to the national income—a redistribution which would fall mainly in the depression phase when large guaranteed wage payments would be made.

How such a redistribution affects aggregate demand is one of the most difficult questions in the whole field of economic analysis. At the present time, there does not exist sufficient theoretical and factual knowledge to permit a confident or precise answer. It involves the same perplexing problem as that of the incidence of the taxes raised to finance our whole social security program; or for that matter, of the incidence of corporate and business taxes in general.

As we have already noted, we assume that any increase in productivity induced by the guaranteed wage has already had its effect in total real income. The problem to which we address ourselves, therefore, is the redistribution effect of the guaranteed wage. Three extreme positions can be stated, with the truth probably lying somewhere in between: (1) The cost of guaranteed wages is borne completely by profit-receivers through reduced earnings of their properties; (2) the cost is shifted forward completely to consumers; (3) the cost is shifted back onto workers, who lose in wage rates what they gain in steadier income.

A survey of the literature on social security taxation would show widespread doubt that most of the increase in pay-roll costs could, except in the shortest run, be at the expense of corporate profits. Economists who have written on this subject seem rather to incline to the belief that the primary incidence would be on wages or on consumer goods prices. We would be rash to attempt a pronouncement on this difficult quantitative question, since not even the two of us would be in perfect agreement as to our rough guesses.

In depression when profits are already low or negative, the heavy extra costs of guaranteed wages are perhaps even less likely to fall in large part on capital. This conclusion is reinforced when we remember that guaranteed wages are to be superimposed on a system of developed collective bargaining, where already labor is attempting to keep wages high and is already taking some advantage of management's ability to pay.

But let us first, for the sake of the argument, suppose that the cost of guaranteed wages does fall largely on profits. Then wage income will be larger, and dividends smaller. Since the bulk of dividends does not go to poor widows and orphans, there will probably be some favorable effect upon the propensity to consume. But the extent of this should not be exaggerated. The difference between the average propensity to consume[22] (and to save) of the rich and poor is known to be very great. But the available evidence from governmental family budget studies seems to suggest that the marginal propensities to consume (and save)—and it is only these which are relevant—differ less sharply between rich and poor than do the average propensities. Dollars redistributed from wealthier common stockholders to workers add something to total consumption purchases, but less than is usually supposed. Nevertheless, to the extent that such a transfer is feasible consumption is thereby increased.

Not all corporate profits are paid out i
dividends. Some go to that other silent partner o
business enterprise, the government. Con
ceivably a shift from profits to wages might lowe
tax revenue and, other things being equal, con
tribute to larger depression loan financing and s
to a slightly higher level of over-all expenditur
in other words to a slightly higher level of effe
tive demand. It should, however, not be hard
find other more obvious ways of expansion if d
pression and unemployment call for expansiona
fiscal policies.

A considerable part of profits goes into net c
porate saving, representing undistributed prof
or additions to earned surplus. Part of the i
crease in guaranteed pay rolls might be expect
to come out of such net corporate saving. (T
is true even in deep depression, when net corpor
saving may be negative if dividends are being p
out in excess of current earnings; because
guaranteed wages the figure might bec

---

[22] "Average propensity" refers to the proportion of income
sumed (and saved). "Marginal propensity" refers to the pr
tion of any small additional increment of income which is
sumed (and saved).

algebraically more negative.) An increase in the payment of wages at the expense of corporate net saving would, taken by itself, tend to raise the level of total effective demand. But this conclusion would be true only on the assumption that there would not at the same time be adverse effects upon the corporation's inducement to invest.

In time of deep depression, most firms do not even replace much of their depreciating equipment. Yet they still, on their income statements, nclude charges to depreciation reserves as an item of cost to be subtracted from gross earnings in ar- riving at net profit. But these depreciation harges are expenses that, at the moment, involve o outlay. It would therefore be wrong to con- lude that a firm which was suffering business osses was necessarily flooding the community with urchasing power. A more meaningful measure f a firm's expansionary or contractionist in- uence, taking all factors into account, would be e difference between its gross investment ex- enditures (including replacement outlays) and s gross saving (including depreciation); or, what mes to the same thing, the difference between s net investment and its net saving.

With net and gross investment already cut to e bone, in a period of depression a further re- ction in earnings (and net saving) might not ve any very significant effect upon net invest- ent. But in the first years of recovery from a pression, or during the first years of descent o depression, there might be some counter- ancing adverse effects upon investment—al- ugh not necessarily dollar for dollar. These verse effects might arise *ex post* simply because an imperfect capital market many firms must pend upon their own funds for their investment lays.

robably more important would be the effects expectations aroused—the adverse effects upon estment decisions at all phases of the cycle. ing the boom, businessmen will be somewhat y of undertaking certain doubtful marginal stments if they expect to be unable to cut their roll when times become bad. The harmful l effects upon the average level of net invest- t over the whole business cycle could conceiv- be greater than the quantitative reduction in usiness saving. Or less. No one can say.

We may sum up the case usually considered most conducive to an expansionary effect of guaranteed wages—where the costs fall completely on profits—by saying that stimulus to the level of purchasing power and effective demand is of somewhat doubtful quantitative magnitude over the business cycle as a whole. In depression times, the quantitative effects may be somewhat more important, but still should not be exaggerated.

Let us turn now, more briefly, to the more realistic case where a considerable part of the cost of guaranteed wages is assumed to fall on wages or upon the consumer's real income. If only seasonal or short rhythms of particular industries are being considered against the background of a full-employment society, such a method of meeting the costs may lead to a more nearly optimal system of pricing and use of economic resources. But from the standpoint of business cycle fluctuations, such a method of bearing the costs of guaranteed wages is fairly neutral in its over-all effects upon production and (real) effective demand.

If the cost falls upon wages or raises consumer goods prices, then income is being shared by those who are employed with those workers who would be without pay if it were not for the guaranteed wage. If such benefited workers are not already in high-paid industries and do not already have high current incomes (apart from the guaranteed wage) this whole process may involve some redistribution of income from average income receivers to those who are more needy. Just as with schemes for sharing work through reduced hours, this redistribution might result in some slight increase in the propensity to consume for the community as a whole. However, the point made earlier concerning the smaller difference between marginal propensities of different income classes would apply here with even greater force—since the difference between incomes is in this case relatively small.

The guaranteed wage would amount, in these circumstances, to a sharing of the income between those productively employed and those unemployed. In other words, those who are earning incomes at productive employment would be defraying the cost of the guaranteed wages. This is all the more true in view of the fact that under depressed conditions, profits could cover no appreciable part of the cost. Thus, the guaranteed wage, under these circumstances, would in fact be a "share-the-income" program. In place of a "share-the-work" plan, we would have a "share-the-income" plan. There would occur a shift of income among the wage-earner and consumer groups with no sizable effect upon the aggregate propensity to consume.

We may conclude, therefore, that a pay-as-you-go financing of guaranteed wages which does not fall on profits would result in little change in the level of income determination at the different phases of the business cycle. With real investment fluctuating over the cycle, real total consumption (all groups in the economy considered) would not remain stable, and real income would still fluctuate more than the absolute variation in net investment. Only to the extent that the cost can be saddled on to corporate profits, and more specifically upon corporate saving and not upon investment, will the guaranteed wage plans have any appreciable expansionary effect upon the level of over-all production and employment.

This does not quite exhaust the analysis of guaranteed wage financing on the total level of effective demand. As yet no mention has been made of the possibility that the enhanced security engendered by guarantee plans might cause workers to save less over the cycle, and to purchase with their savings more durable goods such as autos and houses. This is a possibility, and to the extent that it is effective, it would work toward some strengthening of the average level of effective demand.

Can a similar case be made out for the proposition that the guarantee device will cause employers to cast about for new productive activities and thereby raise the average level of employment? As far as a single concern is concerned, there may be something in this. If a locomotive or other capital-goods producer were to take on a consumers-goods line, such as breakfast food, he would no doubt smooth out the variation of his employment and production. But for the economy as a whole, little or nothing has been gained. The average income elasticity of demand and the over-all fluctuations in income are the same as before. Similarly, if an auto company, to make work for its own employees, cancels subcontracts with suppliers and begins to make its own parts, there is no over-all gain. If the beer industry, by heavy advertising, gains at the expense of the bakery or confectionery trade, the over-all situation is the same. Only too often, the devices which seem to stabilize one concern's production are at the cost of somebody else's destabilization.

The only true exceptions, from a business cycle point of view, are policies which involve additional net investment for the community as a whole, or an expansion of consumption standards. "Producing for stock" is one stabilization device frequently mentioned by writers on guaranteed wages. Such a policy does involve net investment. How important can this factor be over the business cycle? The answer is somewhat discouraging, except for brief cycles. Production for stock might in 1930 have kept employment from slipping off as rapidly as it did. But such positive net investment in inventories is only too likely to result subsequently in commensurate disinvestment, making 1932 and 1933 even more depressed. A brief recession in business believed to be temporary might be bridged by this device. But a sharp inventory recession of the 1921 or 1938 type is likely to be accompanied by so much price uncertainty as to render this device relatively ineffective.

We must also not lose sight of the fact that many of the policies of businessmen that lead to larger total investment and employment do not give rise to much employment within their own plants. When railroads order new equipment, the extra jobs are not provided for railway labor. When a merchant or manufacturer "buys for stock" the task of guaranteeing jobs is eased for his supplier but not for himself. It is true that he is somebody else's supplier, and that if all together pursu expansionist policies, all together may benefit But it is not less true that anyone who holds bac will also benefit from the expansion of the others and it is somewhat Utopian to rely upon collusiv decision-making by business as a body or upo altruistic social planning by isolated businesses

The figures of seven-eighths consumption ar one-eighth saving are given by way of illustratio They should not be interpreted literally, especial since in many downswings of the business cyc autonomous net investment (caused by advanc in technique and the like) will not disappear co pletely. Less than one-eighth of the full e ployment income level would then have to be ma

p by guaranteed wage programs in order to keep
tal consumption stable.

There is also the further possibility that some
ppreciable part of net investment expenditure
not "autonomous" but is "induced" by, or is de-
endent on, the level of consumption or income.
ccording to this type of argument, if guaranteed
ge plans succeeded in keeping consumption at
higher level, then an appreciable amount of net
vestment would be induced (over what there
uld otherwise have been).[23]

The weakness in this argument stems from the
t that a given stationary level of national in-
ne, no matter how high it is, cannot on balance
supposed to include any continuing net—as
tinct from gross or replacement—investment.
is only the change in the level of income that
uces net investment. When the stock of capi-
has become adjusted to any new level of in-
ie, no matter how high, net investment would
in disappear [24]—in the absence of technological
nges and interest rate variations.

hese rather long-run considerations will not
n decisive to the adherent of guaranteed wages
business cycle cure. He will ask, "Isn't the
ness cycle a short-run phenomenon? Would
the maintenance of consumption lead to in-
ed investment (over what it would otherwise
been) for at least the few years that a depres-
usually lasts?"

ie answer to both of these questions may well
the affirmative. But this does not mean that
temporary, once-and-for-all, induced invest-
effects of consumption maintenance can be
rded as raising the average level of demand
employment over the whole cycle. What is gained in investment during the depression is likely to be at the expense of investment during subsequent periods. By virtue of induced investment effects, guaranteed wage plans may have some stabilizing effects on the cycle—by expanding depression demand at the expense of the following boom-time demand. In this it resembles reserve financing, which we are about to discuss, with the difference that reserve financing usually fills in the trough of depression at the expense of the previous rather than the subsequent peak. But neither method is likely to expand demand appreciably over the cycle, unless Government loan financing or private corporation net savings are used to finance the guaranteed wage plans. Moreover, as we have seen, any favorable induced investment effects must be set against the unfavorable effects upon net investment and venture capital resulting from the recognition by potential risk-takers that guaranteed wage plans are likely to increase their costs and risks.

One final point favorable to the guaranteed wage. Over time, the consumption standards of people increase as people get used to higher levels of living. Any success achieved in maintaining high real incomes tends to breed further success. Unlike induced investment effects, "induced consumption" effects may be permanent rather than transient or once-and-for-all.

Once employment is guaranteed, labor becomes in the nature of an overhead cost rather than a variable cost. We should at least explore the possibility that this might lead to a pricing policy over the cycle which would make for greater stability of production. The beginner in economic theory is taught that really fixed costs should, at least in the short-run, be disregarded in output decisions and price formation; any business should not be refused which can at least earn something more than variable costs. If a large part of labor is no longer a variable cost, this might permit downward flexibility of prices to rather low levels.

In more advanced courses in economic theory (particularly those dealing with so-called "administered" prices and monopolistic competition) we are taught that "full" costs (including both overhead and variable costs) actually have an important influence on price formation, and this more sophisticated analysis appears to be in line with business practice and business opinion. In all like-

---

technical terms, some economists would assume a "margi-
opensity to invest" (out of income) as well as a marginal
sity to consume. This would tend to increase the "multi-
effects of a given increase or decline (as the case may be)
onomous investment or autonomous consumption. But so
the two marginal propensities add up to less than one, then
teed wage plans will incur some over-all losses (payments
labor) whenever autonomous investment declines. How-
hose writers who assume large marginal propensities to
and large multipliers, seem to imply that the historical
in autonomous investment (the "multiplicands") were
ondingly smaller—in order to lead to the same observed
ions in total national incomes. Therefore, to such writers
sses" resulting from guaranteed wage plans would tend to
espondingly smaller.

s situation means that there are no changes in technology
g new processes of production or new products for con-
n. Changes in methods of production or in products
ften require new autonomous investment, which would
rise in national income.

lihood, this pattern of "full-cost pricing" tends to characterize those semi-monopoly fields where industry is likely to guarantee wages. Therefore, it is something of an academic exercise to investigate the effect of flexible downward prices which abstractly might be related to the conversion of labor costs from a variable to a fixed cost.

Twenty years ago most economists would probably have considered such downward price flexibility a highly effective way of meeting depression. Today we are not so sure. The modern economy (given our present-day institutions) does not seem to go through price deflation painlessly or easily. Still there is this to be said for the kind of downward price flexibility referred to above in connection with the guaranted wage. Such price reductions would not, it is assumed, be accompanied by wage reductions or any substantial decline in worker income, so that one of the worst aspects of a deflationary spiral would not be present. Still, increasingly it is the modern viewpoint that the price elasticity of demand is much lower in depression periods than used to be thought the case. Consequently, we should think it unwise to attach too great quantitative importance to the phenomenon under discussion even if it were likely—which it is not—that prices will show the proper cyclical flexibility rather than perverse flexibility.

RESERVE FINANCING

We must now analyze the possible effects of reserve financing. This method has most significance, and is most likely to be resorted to, in a society subject to pronounced cyclical swings. If, on the contrary, employment is reasonably stable, whether at a high level with low unemployment or at a relatively unsatisfactory level with chronic unemployment, one year is very much like another, so that there can be little shifting of the financial burden over time.

A gradual and experimental introduction and extension of the guaranted wage plan might be financed in part on a self-liquidating basis. A gradual expansion of the program as experience justified might be accompanied by cost reductions which could "carry" the reserve plan without resort to higher prices or wages lower than could otherwise be paid. On this basis, it is likely, however, that progress toward the guaranteed wage would be slow and would probably be largely restricted to firms whose employment experience is in any event favorable. If anything substantial were going to be achieved, it is probable that there could be no escape from a program involving, for the great majority of firms, the accumulation of reserves financed out of profits, wages, or higher prices. Without substantial reserves, the program would be discredited by a wave of defaults at the first onslaught of any considerable volume of mass unemployment.

An examination of the experience of various firms in the 1929–34 depression reveals how costly different guaranteed wage plans might have been. The high employment commitments of the late 1920's would have entailed heavy cost outlays all through the early and middle 1930's. If guaranteed wages had then been in existence, in a real economic and accounting sense, the men necessary to produce the high 1929 outputs would frequentl have cost the companies in the thirties more thar the total wages actually paid out to them at tha time. Prudent bookkeeping would have suggested that this expense be recognized in 1929 a part of the cost of that year's output, and tha funds be set aside to meet this contingent, bu nonetheless necessary, deferred expense.

Accordingly, if we mean by a guaranteed wag program something more than a cautious an tentative introduction by a few firms with highl favorable employment experience, we must e visage a substantial program of financing— other words, the accumulation of large guarante wage reserve funds. Now it is just this proble which we need to face in assessing the feasibili of the guaranteed wage plan, unsupported governmental financial assistance. How wou the accumulation of large guaranteed wage serves affect the functioning of the economy?

An analysis of the impact of the guarante wage system (financed on the reserve basis) up the flow of income and expenditure involves a c sideration of the manner in which such a progr withdraws funds from the income stream on one hand, and pours funds into the income stre on the other. If we envisage a highly fluct ing society, and if we concentrate attention the moment exclusively on cyclical unemploym it follows that a guaranteed wage reserve will, for the economy as a whole, withdraw fu

from the income stream in boom years, and pour
ack approximately equivalent funds in the de-
ression years. The same problem of "incidence"
f the costs arises here as under pay-as-you-go;
ut the timing is different.

If we assume that the annual charges to the
eserves are financed largely from higher consum-
r prices or lower wages, it follows that the level
f consumer expenditure would be less than other-
ise in the boom years, and higher than otherwise
the depression years. The "reserve method"
ps off the boom and fills in the valley of depres-
on. It is a method of redistributing expendi-
res over the time span of the cycle. The reduc-
on of expenditures in the boom period might re-
ce employment, or it might merely have the
fect of holding down price inflation.

In technical terms, the accumulation of reserves
ring prosperous periods tends to exert a de-
tionist influence at that time by reducing the
ective propensity to consume and increasing
verage thriftiness" or the effective propensity
save. The spending of the reserves in the de-
ession period exercises an expansionist effect by
sing the effective propensity to consume at that
e.

Taken as a package, this double-barreled pro-
m is socially desirable. But if the period of
called prosperity is like that of 1936 or 1937,
other words not one near to full employment,
deflationary influence of reserve accumulation
aken by itself, a factor reducing employment,
sumption, and in all likelihood capital forma-
as well. However, if the prosperity period
ne characterized by manpower shortages, by
much effective demand, and a tendency toward
tion, then the enforced reduction of consump-
is all to the good.

e need not treat in detail the mechanics of
process whereby reserves are accumulated and
ersed, because this problem has been widely
ussed in the literature on social security. If
anteed wage reserves consisted simply of
ing up of cash or bank deposits in good times
their dispersal in bad times, the process would
elatively simple. The quantity of money
d not necessarily have to undergo any changes
ts rate of activity or velocity would be lessened
od times and increased in bad.

If reserves are treated as trust funds investable only in Government bonds or similar gilt-edge securities, the mechanics might be slightly different but the final effect substantially the same. As a matter of fact so long as the Federal Reserve banks or the commercial banks are willing to buy or sell considerable volumes of Government securities, these assets possess many of the liquidity properties of money. If, in depression, the bonds accumulated in the reserve funds were bought by the banks, then the stimulus to effective demand resulting from guaranteed wage disbursals might appear as an increase in total bank deposits rather than simply as a change in the velocity of money. In good times, if the growing reserve funds absorbed Government bonds held by the banks, the result would be to curtail the volume of deposits during the boom below what it would otherwise be.

Any thoroughgoing discussion of this problem would have to take account of the effects upon the interest rate structure of both the accumulation and deaccumulation of such reserve funds. Broadly speaking, these secondary reactions upon the interest rate structure and the capital markets are to some degree perverse. The accumulation of reserves in good times would to some measure tend to raise capital availability and lower interest rates, so that some of the enforced reductions in consumption would seep over into investment rather than curtailing over-all demand.[25] Similarly in depression, attempts to liquidate reserve funds might have some upward effects upon interest rates and consequently, some depressant effects upon investment. However, these secondary effects can be minimized if reserve funds are confined to Government bonds. Moreover, the monetary authorities can easily, and should, take account of any perverse interest and other effects of reserve accumulation and deaccumulation and take appropriate action.

---

[25] So long as the funds are not hoarded, there is always the possibility that some of the purchasing power diverted away from consumption will filter into investment. (It has been argued along similar lines that raising taxes in excess of Government expenditure to retire debt may prove not to be deflationary if the owners of retired Government bonds plough the money back into productive investment expenditure.) In a perfect capital market, where the favorable effects upon investment can only take place through a reduction in the interest rate, this secondary reaction to a primary reduction in the consumption schedule would in all likelihood be quantitatively smaller, dollar for dollar, than the original primary effect. This for two reasons: the doubtful responsiveness of investment to reduced rates of interest, and the adverse effect on investment outlay of reduced consumption sales. To the degree that the actual capital market is an imperfect one, always subject to informal rationing, investment may react somewhat stronger to larger loanable funds than if the investment rate alone were involved. This modifies but hardly alters our conclusion.

A new possibility would arise if governmental fiscal policy could be assumed in the years ahead to be effective in preventing inflation when the economic system is operating at full employment. Whenever private investment demand was excessive, fiscal and monetary policy, on this assumption, would curtail the excess. In such an environment, the widespread accumulation of guaranteed wage reserves would reduce to some degree the need for alternative deflationary monetary and fiscal policies. If carried to excess, however, such reserve accumulations might have to be offset by actual expansionist governmental policies.

There is no assurance that the level of income and employment over the entire cycle would be any larger under reserve financing. Among other effects, the program would bring about a redistribution of income, partly from profits, partly from consumers in general, and partly from productively employed workers to workers who, if there were no guaranteed wage plan, would cease to draw wages. If carried out on a relatively modest scale—one which would not seriously distort price-wage relationships—the effect would be to level off more or less the boom demand and to raise the effective demand in the depression period. But if really huge reserves were accumulated in boom years, adequate to pay annual wages to a large part of the labor force in a depression as serious as that beginning in 1929, the boom could easily be converted into a depression. Reserves of the magnitude required would cause a serious distortion in the economy. Some would prefer to state this distortion in terms of the wage-price structure, others in terms of a concealed tax on consumers and wage-earners, and still others in terms of a savings-investment problem.[26]

Apart from these theoretical considerations is the practical matter that actuarial calculations of the unemployment risk are not feasible. The reserves that are built up might prove too large. In this event the accumulation of reserves would amount to a compulsory savings scheme not simply in the boom years, but also over the entire cycle. Aggregate demand might thus tend to become deficient over the long run and create a condition of underemployment. (Of course if the long-run factors were inflationary, such compulsory saving would tend to be a stabilizing factor.) Finally, in a growing society, the setting aside of reserves, even though actuarially exact, nevertheless would still result in the growth of reserves over the cycle, and to this extent, would tend to aggravate the problem of maintaining adequate levels of aggregate demand.

On the other side, the inability to make reasonably accurate actuarial calculations of the risk involved might result in wholly inadequate reserves. Unemployment insurance reserve funds, though they undertake a very limited liability compared with a comprehensive guaranteed wage program have had to be supported in various countries b the Government treasuries. While large reserve have been built up in the State unemploymen funds in the United States, a serious and prolonge depression could easily bankrupt many of ther A guaranteed wage plan, even one limited to 4 weeks per year, could be considerably more costl than unemployment insurance. The reserv funds, to withstand a serious depression, migl have to be far larger than those needed for uner ployment insurance. Put to the test, guarantee wage plans might need Government support ev more than unemployment insurance. Thus, wh was intended to be a scheme based on priva industry financing might face default under t stress of serious depression, or else be compell to call upon Government support. This ri serves to stress all the more the importance of imiting the employer's liability, as suggested in hapter VI below.

---

[26] If technological cost savings from the guaranteed wage plan (assuming for the moment that such plans do increase man-hour productivity) were placed in a reserve fund during the boom phase of the cycle and paid out in the depression phase, the effect would be a redistribution of income over time. The total income payments made to individuals in the boom would be made less than would otherwise have been the case; and during the depression the income payments would be increased. Financed as here assumed, out of increased productivity, there would result no redistribution of income between individuals, and no absolute reduction in corporate profits or corporate net savings. If however, the gains in productivity were nil or inadequate to cover the guaranteed wage payments, the added costs would have to come either out of corporate net savings or else from a redis bution of the income of individuals.

Only the reserve method of financing is capable of redistri ing the income over time, i. e., from boom to depression. redistribution over time has nothing to do per se with the q tion where the funds come from, whether from: (a) gain productivity or (b) redistribution of income between individ and social groups. If the reserve method of financing is used, gains from productivity will necessarily be passed on i form of (a) larger income payments, (b) increased outlay plant and equipment, or (c) larger corporate retained earn But none of these, apart from reserve financing, would to iron out the cycle.

It would not be possible to calculate with any igh degree of accuracy the actuarial risks involved n introducing guaranteed wage plans in different ndustries even in a society committed to a program f sustained full employment, and prepared to use scal, monetary and other measures to achieve this oal. A number of countries, including England, anada, and Australia, have issued white papers n employment policy proclaiming high and stable vels of employment as a deliberate aim and sponsibility of Government. The United States mployment Act of 1946 does not go quite that r. All the British countries referred to above ve recognized the difficulties involved, and none confident of anything more than moderate suc- ss. Thus, even with the best of good will and vorable circumstances, no one knows what gree of success may attend these plans. We ow that the war has left us the heritage of numerable distortions, and these will plague us many years to come.

Let us suppose, however, that we have surpassed s difficulty—that experience has, in fact, demon- ted a high degree of success with a stabilized l-employment program for a period sufficiently g to warant general confidence. Some fluctua- s there would nevertheless be, but more moder- and presumably fairly well under control. lical fluctuations of employment would be l, yet relatively large in the heavy capital- ls industries. Seasonal and transitional un- loyment would also be experienced.

the "ideal" society described above (and we at that we have no illusions that such a society quickly be realized) guaranteed wage plans, ately financed, might tend to moderate any re- ing cyclical swings, and to facilitate an at- on seasonal unemployment. Transitional frictional unemployment might be intensified e guaranted wage had the effect of reducing mobility.

ithin the framework of the society envisaged , cyclical unemployment might become a or less manageable risk, and accordingly, the ve funds needed to meet the financial liability involved would not need to be large. In this event there would develop no long-run problem of excessive compulsory saving in the form of reserve funds. The reserves accumulated in the good years would be dispersed in the relatively low years. This leveling process would tend to smooth any remaining swings in the cycle.

A buoyant labor market, such as that here assumed, would moreover be favorable to an attack on the problem of seasonal unemployment. Employers would be stimulated by the introduction of the guaranteed wage to find year-round work for their employees. It is one thing to place such a responsibility upon employers in a society such as the one we are living in, with its grave uncertainties with respect to the stability of the market and the adequacy of aggregate demand. It is quite a different matter to introduce the guaranteed wage in seasonal industries in a society in which, within reasonable limits, the adequacy of aggregate demand is assured. The development of supplementary lines is feasible in an expanding and buoyant society, whereas it might only supplant the product of some other producer in a limited market in which there was not work enough to go around. Seasonal unemployment might be largely eliminated in a full-employment economy. But even so, this important goal could not be reached unless ingenuity and resourcefulness were brought to bear on the problem. The guaranteed wage might offer a powerful financial inducement to employers to find steady year-round work for their employees. The technical job of dovetailing short-run fluctuations in employment is no mean managerial task, but a sustained high level of aggregate demand would provide an environment within which the job could be attacked with high promise of success.

We have spelled out these various prospects of the guaranteed-wage program within the framework of a society which had achieved a high and stable level of aggregate demand, not because we think such a society is going to be reached tomorrow or the next day, but rather to lay bare the difficulties confronting the guaranteed-wage program. The conclusion is not that the guaranteed wage must await the dawn of a perfect society. The conclusion is rather that we must take account of its limitations, and especially avoid procedures that may defeat the very purposes which it is intended to achieve.

Having in this chapter analyzed the effects of guaranteed wages upon the problem of business-cycle unemployment, we turn in the next chapter to a consideration of its influence upon the pricing system as it relates to the efficient use of economic resources. Even if the problem of depression were brought under control there would still remain the challenge of seasonal and other irregularities in production.

V. GUARANTEED WAGES AND EFFICIENT USE OF RESOURCES

The problems to be discussed in this chapter are of a rather abstract and general nature. Nevertheless, the theoretical analysis involved, even though briefly stated in this report, is, we believe, important in an over-all consideration of the guaranteed wage.

THE MERIT-RATING CONTROVERSY

In chapter II it was shown that the economic cost of idleness to the community could be primarily measured by the loss of output which it entails.[27] Suppose that a particular industry or line of activity has a record of great instability of production and employment. How should its prices and costs then be set?

This identical question was involved in the extensive discussion of merit (or experience) rating in connection with unemployment compensation. The original Wisconsin Unemployment Insurance Act, drawn up under the strong influence of John R. Commons and economists of his school, required employers with unusually poor records of stability to pay higher rates of taxation. Those demonstrating unusually good continuity of employment were granted lower rates—in much the same way that steel-frame buildings, relatively immune to fire risk, are granted low fire-insurance rates.

Two principal considerations are usually invoked to justify this procedure. First, and perhaps of least importance, is a feeling that fairness (justice or equity) implies that an employer should have to pay only for the evil which he creates, but that he should be made to pay for that. This particular argument is a highly controversial one. Numerous writers, perhaps even the majority, have dissented, arguing that it is the essence of social insurance (in contrast to private insurance) that there be a sharing of burdens between groups; the essence of merit rating, on the other hand, is the perverse principle of "to him that hath, shall be given."

The second argument in favor of making the industry bear the costs of its own instability has usually been the more important one. Under such a system, management is supposed to be encouraged to stabilize its operations. It is financially penalized if it does not stabilize; it is rewarded to the extent that it does. There is certainly something to this; as we saw in our earlier discussion of the present wage contract, labor appears to each firm as an avoidable variable cost. Current practices therefore tend to warp and distort the socially desirable adjustments of production.

We do not wish to enter upon the details of thi controversy. It is enough to note that the opponents of merit rating point to empirical data t show that employers are typically not able to d much about their own instability. Experience, is said, seems to indicate that employers' reaction to higher penalty rates are not sufficiently sensiti (particularly in response to the rather modera differences in rates usually involved in merit ra ing) to be very significant. Further, it is argu that employers with steady records are not usual better planners but are more often the lucky ben ficiaries of special market situations (often of monopoly type).

This economic controversy finally burned down in the years after 1935 when the Social Secur Act was passed. The theoretical honors, if e may judge from the literature, seem to have g ne against merit rating. Nevertheless, in rec nt years merit rating has been introduced in modi d form by almost all States, principally as a e-way street making for reductions in taxation nd tending to keep unemployment reserves f m growing so rapidly during the high-employm nt wartime years—that is, during precisely the m when such reserve accumulation might contri ute

---

[27] Our earlier discussion also dealt with the additional evil arising out of the effect of idleness itself on the worker and community, and also upon the problem of equitably sharing the costs involved in idleness between different individuals and groups.

oward the fight against inflation and excess aggregate demand. This, and not the establishment of
ffective differentials spurring planning for sta-
ilization, has become the primary function of
ierit rating.

BUSINESS CYCLE VERSUS OTHER IDLENESS

When we turn to guaranteed wages, which is
quivalent almost to 100-percent unemployment
mpensation borne completely by employers,
hat was previously a rather stale academic exer-
se becomes a really vital economic problem.
ould the form of the wage contract be changed
as to raise, substantially, the costs of production
unstable firms?

A quite different answer must be given to this
estion depending upon the kind of instability
olved. We saw, in the last chapter and earlier,
t a typical business concern cannot really do
y much by itself to moderate the cycle, and
en what it can do represents no corresponding
gain for society as a whole but rather only
nges the place where instability appears. We
saw that widespread guaranteed wages by all
loyers together are scarcely likely, taken alone,
prove a quantitatively important stabilizing
or in an economy subject to wide swings of
estment, which in turn have a cumulative effect
ncome and employment.

he John R. Commons view that the price of
commodity should be made to bear the cost
he idleness which it involves—we do not say
es—cannot validly, we believe, be applied to
ployment of the business cycle type. In this
ter, we wish to consider whether or not a
ar conclusion would hold with respect to un-
e industries which operate in a continuing
employment economy; or to unstable indus-
which operate in an economy whose general
all activity is steady but at a relatively low
involving considerable chronic unemploy-

the risk of being wearisome, let us repeat once
why the problem of business cycle unemploy-
differs from that of seasonal or other ir-
r rhythms. The unstable sector of our econ-
s predominantly the capital goods industries.
gue that costs and prices should be raised
h industries flies in the face of certain commonly accepted programs for fighting depression—programs which stress the need to reduce construction costs, interest rates, and capital costs in general so as to stimulate investment outlays. It would be bad social accounting to discourage employment in the capital goods industries by saddling additional costs on these industries. Such a procedure is only too likely to reduce the total volume of capital goods outlays over the cycle, thereby leaving the system at a lower average level over the entire cycle.

The same matter may be put in still another way. When unemployment is the alternative to an industry's employment of a worker, the true social (opportunity) cost of hiring the worker is nil. Let us suppose that we undertake to saddle—in the form of an overhead—the financial cost of an idle worker upon the industry in question. If indeed, it were true that the capital goods industry were characterized by a high degree of perfect competition, in the short-run these increased overhead items would not cause any increase in the selling price of the product (a capital good) since under perfect competition the selling price would be forced, in periods of falling demand, down to a level below full unit costs. This means that saddling the extra labor cost (in the form of an overhead item) need not necessarily result in curtailment of output. Instead, it would cause the short-run burden to fall heavily upon the industry's stockholders. This might well be better than having it fall upon the workers, but is not necessarily better than spreading the burden of depression more widely on the community as a whole (assuming for the moment that the Government does not act to prevent depression).

The above result would hold only for a highly competitive industry and then only for the short run. In the longer run, firms would be forced out of the industry as a result of chronic losses (incident to saddling the industry with extra labor cost in the form of a guaranteed wage overhead) until enough firms had left to cause output to decrease and prices to rise to the level of full average cost (including overhead and taken over the whole business cycle). But such increases of the price of capital goods, as we have already seen, tends to reduce total employment.

If the industry is one characterized by considerable imperfection and by administered prices set by the firm, we might still have short-run ruinous competition. But more likely the firms will be aware of their competitive interdependence in pricing and of their monopoly power to raise prices without losing any considerable part of their customers. Full cost considerations are likely to provide a powerful rallying ground for the firms in the industry, so that, even in the short run, prices might rise. In the long run, the same result as already indicated would follow, although we must also be prepared for the possibility that so-called monopoly profits may be made to bear part of the cost.

In the absence of effective Government full employment measures,[28] it would not be good policy to permit the whole scale of capacity and labor force in the capital goods sector to shrink to a point where the average price over the cycle would cover full costs including the guaranteed wage overhead. This might only make the saving and investment problem worse.

And yet, it is patently unfair to let workers (attached to the capital goods trades and who have no other place to go) receive lower earnings over the cycle than other workers. One obvious solution would be to let the Government make up the difference in relief payments or social insurance, it being manifestly undesirable to permit capital goods prices to rise over the cycle. However, if the policy of Government aid is to be followed, it becomes rather obvious that the Government might better get something for its money in the way of useful public projects. Thus we are brought to a planned program of public expenditures to fight depression; or if the people democratically feel that high priority should be given to private consumption activity, the logical policy implication is Government transfer expenditure (or tax reduction) which will increase private consumption and thereby provide job opportunities outside of the construction and capital goods industries. And just as taxes should be raised during inflation and Government expenditure carefully trimmed, so in lean times tax reduction is in order, while useful governmental investment and public services will need to be expanded.

CONDITIONS OF CHRONIC UNEMPLOYMENT

But what if there is no effective full employment program and the economy operates at a steady level with considerable unemployment? How does the view that the prices of unstable industries should be made to bear the costs of their instability then stand up?

It will be clear from the discussion above, that the answer must be "very poorly." In effect we are asked to place a sales tax on the capital goods industries in order to keep up the income of the unemployed. This is very nearly the worst type of financing that anyone could devise.

OPTIMAL PRICING UNDER HIGH EMPLOYMENT CONDITIONS

When we deal with a world of adequate aggregate demand and generally high employment however, the John R. Commons reasoning come into its own. Then any industry with grea seasonal variability or with some other irregula pattern will be withdrawing the labor it hire from other productive employment.[29]

In a high employment economy any industr that draws resources to itself and then uses the only part of a year ought properly to be charge with the cost of those resources. This industry output must bear the responsibility of causing r ductions in output elsewhere, equal in value to t productive resources taken away from all oth industries.

Even if an industry is unable to stabilize s operations, it should still be charged up with s full costs, inclusive of idleness created by t. Otherwise too many resources will be going i o that industry, its price will be too low, and the c sumer of the goods in question will be subsidi d at the expense of the group least able to afford e ourden—the workers subject to intermittent in- ome. Higher costs are more than a whip to the mployer; they are a device for contracting an nstable line of activity.

---

[28] We deliberately refrain from discussing the problem of letting wages (and prices) fall in an attempt to reduce the surplus supply of unemployed labor. Such a discussion would be highly technical and would involve a volume by itself. Except for a small fringe, the majority of writers dealing with this problem in the last decade are of the opinion that cutting wages and prices in a hyper-deflation spiral is either undesirable or unfeasible (or both) in a modern capitalistic country. It will be clear from our emphasis that we believe that any alleged advantage of such a deflationary process could better be achieved by expansionary policies.

[29] These remarks are not meant to apply to those season in- dustries which hire workers who come for limited periods to the labor market, from schools and from homes. Such indus ies perform a highly useful function in providing short-perio em- ployment at just the season of the year when there occ a temporary increase in the labor force.

If it is unavoidably necessary for a municipal reman or an auto worker to stand by in idleness uch of the time, we must redefine our concept of roductive labor to include such necessary "ac- ivity." At the same time we must tender to the uto worker what we already concede to the fire- an, adequate pay for all working time that he unable to perform elsewhere.

Undoubtedly the gradual carrying out of a pro- ram such as is implied in the above remarks would sult—gradually but surely—in some drastic antitative changes in the present pattern of ices and output. So much the better, if it is ue that the present-day structure of prices is ossly distorted away from an efficient and equi- ble pattern of resource use.

Some people may grant that an industry should charged with the full cost of the resources it kes away from other industries, but still argue at higher hourly wage rates rather than a longer aranteed tenure is the proper solution to the oblem. The statistical data referred to in chap- II suggest that there is no universal tendency hourly rates to rise so as to compensate for iability of employment. However, it is un- btedly true that in some very seasonal lines, rly rates are very high; and variability of work one reason offered by unions for even higher rly rates. Often such unions are opposed to ranteed wages, if this is to mean lower hourly es or slower increases in future hourly rates. n such situations, higher hourly rates may be er than no adjustment to heavy seasonal unem- yment. But so long as steady work does not olve extra disutility, the longer tenure provided guaranteed wages would be a more economically ient arrangement because then, and only then, ld there be an incentive toward regularization mployment, an incentive to put the available ker to some sort of useful work.

he only real economic drawback to guaranteed es in such a situation arises out of the very possibility that the workers laid off by the stry in question might possibly (had there no guaranteed wage) been able to find fill-in luctive employment elsewhere. Such possibilities are no doubt limited, but to the extent that they exist, it is not proper to regard the industry in question as being responsible for totally withdrawing labor from other useful work; it is therefore incorrect to saddle the industry with their full guaranteed wages. In fact, in such situations, the guaranteed wage can have harmful effects on the mobility of labor. Our proposal of chapter VI with respect to "integration" with the unemployment insurance system may remedy this in part.[30]

DOVETAILING AND LARGE MONOPOLIES

To the extent that the idle time of the workers hired by one industry can be dovetailed with the operations of another industry or with schooling and leisure, we need not attribute to the industry the full cost of its laid-off workers. Ideally, dovetailing of activity is one solution to the irregularity of seasonal and other short rhythms of different industries. Hence it is essential that unions relax their objections to changes in function and activity of workers.

Dovetailing is easier the larger the units, since when many intermittent lines of activity are merged, the extremes of their sums is much less than the sum of their separate extremes. Or to put this in another way, by merging activities we can cancel off the peaks of some against the troughs of others. This would seem to provide some argument in the direction of large-scale monopolies, necessarily possessed of tremendous amounts of economic power. And so it does, if the dovetailing is to take place within the firm; i. e., if the work is to be brought to the worker and not the worker to the work.

However, dovetailing tends to stabilize primarily to the extent that the components dovetailed have different cyclical rhythms and phases; in the ideal case of the coal and ice dealer, the components will have opposite phases so as to be mutually canceling. Therefore, the firm which wishes to stabilize its time-profile of production cannot do so simply by growing in scale or by adding closely duplicating lines subject to the same timing of demand. It must branch out into new territories, take on new and different lines. Consequently, the fact that it grows in size need not entail a commensurate growth in its monopoly power. Monopoly power depends primarily upon a firm's relative importance in comparison with the total demand for each of its products. If it grows by branching out into new lines the firm is also spreading itself over wider areas of demand. To revert back to the coal and ice dealer, there is no special reason to believe that his monopoly power in either of the two markets is greater that that of two separate dealers each handling one line. His over-all efficiency may be greater; but that is a good thing rather than a bad.[31]

---

[30] Workers in some lines of activity may prefer intermittent employment. To the extent that they value occasional periods of leisure, they need not receive a full annual wage. No doubt collective bargaining in such cases will have other goals than a guaranteed wage.

POOLING LABOR RESERVES THROUGH A WELL ORGANIZED MARKET

If we pursue the argument concerning the desirability of pooling the labor reserves of many lines of activity in order to minimize unnecessary idleness, we are confronted with the problem of the general labor market itself. We can conceive of a vastly improved labor exchange to which workers go for placement. In the fantastically extreme case where each day every person and every firm turn anew to the central labor exchange for reassignment, idle labor reserves would be at an absolute minimum, the whole being steadier than its parts.

Common sense tells us that there are insurmountable objections to such a fantastic case. In any factory this morning's production will depend upon yesterday's activity in such a way that entirely new men coming into the plant would be at a great disadvantage, however good their general experience and training. Moreover, even if the inefficiency of such an arrangement could be overcome, we must still reckon with the intrinsic properties of human nature; the worker would find it profoundly distasteful and disorganizing to move on to a new job at frequent intervals; man requires continuity in his working as well as in his home life.

We need not prolong the discussion of what is admittedly an extreme case. There is no reason why a proposal to pool all workers together into one organized market should not be perfectly compatible with job continuity for the great majority of workers, most turn-over being confined to the "marginal" workers as is now the case. But this discussion does high light the problem of reconciling job continuity for the individual with maximum national productivity.

Thus, if guaranteed wage plans were universally adopted prior to any successful attack upon the problems of stabilizing production, the effect might be to attach workers to a given firm when there was no useful work for them to do there, even though, at the same time, there was productive employment to be found elsewhere.[32] Boondoggling is boondoggling, and bad economic policy whether it is pursued by the Government or by private enterprise. Boondoggling is particularly costly during periods of high employment when productive employment opportunities are plentiful.

This illustrates that it is as necessary in thi chapter, as in the last one dealing with aggregat demand, to distinguish carefully between the different conditions of economic life upon whic guaranteed wage plans impinge—between hig employment and depression economies. There i a danger that guaranteed wage plans, not couple with effective stabilization planning, could immobilize men in such a way as to increase labor hoarding and the inefficient use of resources.

STABILIZATION AND DIFFERENTIA PRICING

Thus far we have been discussing the costs unavoidable idleness. Even if employment we not stabilized, guaranteeing steady wage inco might so improve labor productivity and tur over rates as to be, in effect, costless. This wou be all to the good. Of course, it would be bet still if in addition to making labor more prod tive while at work, it were also possible to fi useful continuous work to do.

Stabilization may, however, be costly at the o set. It takes effort and planning. Under e present wage contract, which permits the layi off of workers on short notice, there may be lit if any, counterbalancing savings of cost from steady operation.[33]

---

[31] Those who regard "bigness" per se as an evil, without regard to its market consequences, may still object to the firm's growth.

[32] Because of the considerable difficulties and costs involv in workers going from one job to another in order to utilize eir special skills, there is also much to be said for mobility o he part of the employer in shifting between production lines r er than throwing the full burden of mobility upon the wor rs. This in no sense means that we minimize the importance of bo mobility between and within firms.

But under the more optimal system of pricing discussed in earlier sections, where each employer is made to pay full wages to all workers whom he withdraws from productive employment elsewhere, the costs of stabilization will often be lower than the costs of not using the workers whose ay goes on anyway. Accordingly, stabilization lans, under this procedure, might be promoted. Being available, such workers might as well be ised for whatever useful goods they could produce. nder high employment, the ingenuity exercised y an employer in financing odd jobs, or less than ully productive tasks, for his men to do in offeasons is highly commendable.

The construction industry provides an illustraive hypothetical case to show how guaranteed ages might give rise to a different system of ricing, leading to a more efficient and equitable se of our national resources.[34] Let us suppose at a house requires, say, 2,000 man-hours of labor build in the summertime and 4,000 in the winr. If labor can be hired and fired by the season the same hourly rates, say $2 per hour all year ound, no one would ever build in the winter, ecause by waiting until the following season, e buyer could save 50 percent in labor cost. onstruction workers would be out of jobs for, say, months of the year. Houses would be sold for ss than their true social cost, most of the differce coming out of the workers' loss of income.

Theoretically, it might be alleged that a way t of this situation would be for workers to acpt half wages in the winter. But in view of ion insistence on uniformity, and if it were asmed that similar workers on steady jobs elseere receive around $1.50 per hour, we may ret this suggestion as unrealistic.

Under a system of guaranteed wages the employer would realize that his summer contracts really involved more than the wage rates paid then. Moreover, during the winter his labor force would cost him nothing extra if he kept it at work. The result: He would produce houses all year around, selling them in all seasons at about the same price (based on the hourly wage times 3,000 man-hours, the average between winter and summer labor requirement). If the old hourly wage rate were retained, the labor cost of a house at the site would now be $6,000 summer and winter. This increase in price results from the product bearing its full economic costs.

However, if part of the $2 hourly rate represented a premium to compensate for the winter idleness, and if similar labor elsewhere received only $1.50 for steady jobs, then the hourly rate might now fall and workers would still be better off than under the old regime with a winter lay-off. Their annual take-home pay would be up by 50 percent. The labor cost (at the site) of houses, summer or winter, would now be about $4,500 (or 3,000 times $1.50), which is just where it should be.[35] Apart from the social desirability of subsidized low-cost housing, the price indicated would draw the right amount of resources into the building industry, and all of such resources would be efficiently used.

This is only a numerical example; it is meant to be illustrative rather than to describe an actual situation. Moreover, it assumes a condition of adequate aggregate demand and high over-all employment so that the excess labor in the unstable, seasonal industry could readily find jobs elsewhere, once the industry were stabilized.

Often a system of variable pricing may prove to be economically optimal. Such a system would mean high prices during peak demand seasons when (marginal) costs are high and output must be rationed; and lower prices during off-peak periods. In addition to price reduction, terms of sale and delivery may be made more agreeable in off periods and less agreeable in peak periods. Alternatively, a seller in peak seasons may offer a reward in terms of priority in delivery dates to

---

One saving, mentioned earlier, results from the fact that less nt and capital equipment are necessary when loads are spread nly over time. Against this saving in interest and deprecia- (resulting from time rather than use) there is the fact that many industries the extra capacity serves as a standby; in of heavy sales, the busy season is lengthened. A plant oping near to capacity all the time cannot expand its production this way, but must depend on overtime or more intensive luction.

As indicated in ch. VI, we do not think that any union should ompelled to adopt guaranteed wages except through voluntary ective bargaining. However, the present hypothetical case of construction industry throws some light on the economic debility of collective bargaining taking one form rather than her.

[35] In a moment we shall consider the possibility of seasonal variations in demand, giving rise to different prices at different seasons.

those customers who have bought steadily in off periods. To be effective, and profitable, the process of stabilization may require something more than rewards to good customers; it may also be necessary to apply penalties to bad ones. And the firms may be compelled to refuse the casual business of new customers at the peak of a sales boom. Were our markets not so imperfectly competitive and characterized during normal times by "buyers' markets," businessmen would realize more keenly that peak-load, fair-weather customers are often very expensive customers who do not pay their way.

Most of the above patterns of price and market behavior have already been tried on a limited scale. Often they have later been abandoned because they were not economical. It might well prove to be otherwise in a world of guaranteed wages, where the penalties for unstable production would be considerably greater than at present.

VI. POLICY RECOMMENDATIONS

The analysis of previous chapters shows that there is much to be said for guaranteed wages, particularly for seasonally or otherwise unstable industries operating in an economy with relatively high and stable levels of aggregate demand. But it also suggests that guaranteed wages cannot be regarded as a cure-all for depressions. There are important limitations to the device as an anti-depression measure—especially in comparison with other economic policies such as fiscal policy and other full-employment programs. In view of these limitations, so long as our society suffers from rather wide fluctuations in business activity, guaranteed wage plans should be introduced only with proper safeguards.

This conclusion is so important that we think it worth restating in a slightly different form. We do not believe that the limitations referred to above warrant the conclusion that guaranteed wage plans are economically unsound and should be abandoned as goals. However, these reservations are sufficiently important to put us on guard against viewing the guaranteed wage as a solution for the problem of unemployment; and especially to warn us that it cannot and should not become a substitute for social security measures or a full-employment program. In this concluding chapter, we should like to put forward for discussion four policy recommendations.

Recommendation No. 1. *Guaranteed wages should be a matter for voluntary collective bargaining without legislative compulsion by the Government.*—Our analysis has not led to the conclusion that the Government should seek to intervene actively by legislation to require that industry introduce guaranteed wages. In the present state of our economy, this is a matter that should be left to voluntary free collective bargaining between management and labor.

Recommendation No. 2. *In many lines guaranteed wage plans may properly include limitations as to the employer's liability.*—From our previous analysis, and from a factual survey of earlier depressions, it appears that unqualified guaranteed-wage plans, indiscriminately applied to industries subject to wide cyclical swings of demand, might involve such extensive financial costs as to prevent industry from undertaking such programs; or if industry had nevertheless undertaken such programs, they might have t be prematurely abandoned in order to avoi insolvency.

Some sort of limitation is therefore necessary Existing guarantee plans provide for variou kinds of limitations: coverage of less than a workers; guarantee of work for a limited numbe of weeks per year (for example 40 weeks); gua antee of less than full-time weekly pay for week covered; provision for nonrenewal of the guara tee; and so forth. What is above all needed, ho ever, is a form of limitation which will in norm times give a maximum of security and protecti to the worker, and to the employer a maximu incentive to stabilization efforts; but which, emergency times, will come into effect to keep t firm's financial liability under the guarante wage within reasonable limits.

Because of the ever present danger of cycli slumps we tend to look with favor on some s of limitation on the percentage of the total gu anteed pay roll that the firm shall be liable for any year or contract period. So long as product declines are not too great, workers will receive percent of their full normal income. But if when deep depression years come along, and lay-offs from productive work involve more than, say, 10 percent (or some other suitable ratio) of the guaranteed payroll, then the workers may have to receive something less than the full guarantee.

The precise percentage liability is a matter for experimental determination over time, and would no doubt vary from industry to industry depending upon their differing degrees of cyclical variability.[36] For many lines of activity, 10 percent nay be a reasonable percentage limitation.

With such a limitation, it should not be necessary 'or private industry to accumulate unduly large eserve funds. Moderate reserve accumulation nay be considered necessary for prudent financial nanagement; and, if not excessive over the whole eriod of the cycle, the accumulation and subse-uent expenditure of the reserves may contribute o dampening the business cycle, helping to con-act excessive boom-time purchasing power and o expand it during depression. But if ever the uaranteed wage should be widely adopted, and if ubstantial private reserve funds were accumu-ted in addition to the continually accumulating overnmental reserves for old-age security and nemployment insurance (currently around 14 llion dollars) the problem of maintaining high mployment might be made more difficult.

Momentarily, the continued growth of these cial security trust funds is helpful as an anti-flationary device. Nevertheless, over the long ll we believe these programs should be placed ore nearly on a pay-as-you-go basis. Similarly, should not like to see a long-run accumulation large guaranted wage reserve funds. Whether social insurance or guaranteed wages, moderate erves that could be drawn on in the depression ase of the cycle would, however, not only be missible but desirable. They would help to ve as an automatic anticyclical compensatory chanism.

Within the collective-bargaining contract itself, re would probably have to be included certain cial stipulations further limiting and qualifying the guarantee of work. For example, there might be a stipulation that wages would not be payable to workers out on strike. Collective-bargaining clauses might be introduced into the guarantee also limiting wages of workers in the plant, not themselves on strike but rendered unable to work by virtue of strikes outside the plant—or for that matter inside the plant but in another department or craft. Thus a transportation strike might so impair the flow of supplies as to make a continued guarantee unbearably costly. All these are matters for free collective bargaining.

The primary purposes of guaranteed wages are to insure workers more security and promote stability of production. The device is not intended to create permanent quasi-feudal rights of a worker to a given job. Thus, if a sweeping technological change makes it no longer necessary to keep the previous number of workers attached to an industry or firm, or if there is a secular change in people's tastes and demands, then the guaranteed wage should not serve to freeze workers to their old jobs and techniques and to thwart our economy's increases in efficiency and responsiveness to demand, upon which the ever-rising standard of American living fundamentally depends.

Most changes are not introduced discontinuously and suddenly. The normal attrition of the labor force of a firm, through turn-over and separation, makes it possible to reduce gradually the number of workers without undue lay-offs. Where this is not the case, the guaranteed wage, together with severance pay, may perhaps be used to soften the impact of the socially-desirable process of change upon the workers directly involved. But we feel it necessary to point out the danger that, with guaranteed wages introducing length of tenure as a new variable in the collective-bargaining negotiation, the long-term flexibility of our economic system may be impaired unless organized labor is willing to waive or limit the scope of the guarantee in situations involving permanent changes in technology and demand.

Recommendation No. 3. *Corporate income tax law and practice should be changed so as to encourage guaranteed wage programs.*—Under present tax law and practice, corporations may for tax purposes deduct as an expense all payments made to workers under guaranteed wage programs, during the year when such payments are

---

The Latimer Report on guaranteed wages presents data show-what the costs to a number of industries of an unqualified antee would have been in earlier years. See ch. VIII, pp. 70–
The report discusses the rather intricate problem of how guaranteed wage funds are to be allocated among the laid-off ers whenever the drop in production turns out to be great gh to bring the percentage limitation into effect.

made. Suppose, however, that a corporation wishes in good times to set aside a reserve fund in anticipation of the time when it will have to pay out guaranteed wages to the workers it is currently hiring. Such appropriations to guaranteed wage reserve funds—unlike retirement pension and profit-sharing programs—cannot now be treated as an expense to be deducted from taxable earnings in good times; only later, when actually paid out, can they be so treated.

The present tax situation is, therefore, in a sense discouraging to guaranteed wage plans. It is, however, easy to exaggerate the quantitative importance of this whole matter. A few years' delay in receiving a tax reduction or credit means primarily the loss of interest on the sums involved. This is all the more true to the extent that corporate income tax rates remain stable, and to the extent that a system of carry-forward (and carry-back) is in force so that the accounting period for tax purposes becomes longer than a year and variations in income are averaged over a longer period.

There seems to be no question that any change in existing practice would require new legislation by Congress. This might take at least two possible forms. First, Congress might specifically provide that any guaranteed-wage payments might be carried back over previous years as deductible expenses. In effect, the company would be reimbursed for its previously overpaid taxes, resulting from its previously overstated earnings—overstated because the accruing liability for guaranteed-wage payments had not been recognized as an expense of production at that time.

A second method of handling this problem would be to permit appropriations to the reserve fund to be deductible as expenses during the year when they are being set aside. Then, later when the reserve is being used to finance guaranteed wages, such outlays would not again be chargeable as an expense and as a tax deduction—for, otherwise, there would be an unwarranted tax loss to the Treasury and an unfair subsidy to the guaranteed-wage plan. So far this second plan seems simple enough; but under some circumstances difficulties may arise. What if more is appropriated to the reserve than is ever necessary to meet guaranteed wages, either because of good luck, or because of good stabilization planning by the employer, or because the employer deliberately builds up an excessive reserve? Certainly under these circumstances it would be wrong to permit the employer to recover the excess reserves, and to escape corporate income taxation completely on the sums involved. For this reason, it would be necessary to insist that the reserve be a "trust," created to provide guaranteed wages or other benefits for the workers. The trust would necessarily have to be irrevocable as far as the corporation was concerned.[37]

Our previous economic analysis and the specific accounting aspects of guaranteed wages justify, we believe, the recommendation that the present tax deterrents to guaranteed wages be removed by one or another of the above described methods: that is by a specific carry-back on guaranteed wage costs, or by tax deductibility (with safeguards) of appropriations to guaranteed wage reserve funds.

Recommendation No. 4. *Social security legislation should be altered so that guaranteed wage plans can be integrated with the unemploymen compensation system to the mutual advantag of each.*—Guaranteed wages should never be looke upon as a substitute for our existing unemployment-insurance system. This system admittedl needs substantial improvement and strengthenin And we believe that guaranteed-wage plans if integrated with social security could operate in th direction. Such integration would serve strengthen rather than weaken the system of u employment insurance.

The workers of employers who maintain wa payments under guarantee plans should be pe mitted to draw unemployment benefits, provid that they are unemployed in the sense that woul qualify them for unemployment compensation the absence of a guarantee.[38] If the employ had to pay only the difference between the f guaranteed wage and the amount paid by the u employment insurance system, then he might more willing to undertake such wage guarant and more willing to broaden the coverage and tend the duration of the guarantee.

---

[37] Any excess reserve funds might be finally used up in all further appropriations to the reserve fund were curtailed. If even this does not meet the problem, the terms of the trust should stipulate that any remaining excess funds be used for the benefit of the workers through providing old-age pensions or for some other welfare provision now permissible from the tax standpoint.

[38] Some important technical and administrative problems are to be faced. These are discussed in Mr. Latimer's report.

Moreover, the employer would then be in the position of wishing to support the extension of Social Security instead of—as under the present system of merit rating—having a financial in- erest in keeping its benefits limited. The only lternative to the method of "integration" here roposed, that would tend to remedy the present iscrimination against the employer who volun- arily agrees to guarantee full incomes to his idle vorkers, would be the method of further extending erit rating—perhaps to the point where all em- loyers with effective guaranteed-wage plans ould be excluded completely from all unemploy- ent insurance taxation. We should consider the doption of such an alternative as something of a lamity, designed to divide and weaken the rces making for an effective social security sys- m.

The method of integrating social-insurance nefits with guaranteed-wage plans would have st the opposite effect, as we have already indi- ted. It would serve to strengthen rather than aken our social-insurance system. In addition, e integration with present unemployment com- nsation would have the further advantage of lucing the tendency for guaranteed wages to eeze workers to a given employment when it may socially desirable for them to transfer to other occupations. Under the integrated plan, in order to draw unemployment benefits, workers would have to be registered with the central employment exchange, and would be obliged to accept suitable alternative employment. This would lessen but not obliterate the tendency for 100 percent income maintainance to have deleterious effects upon the mobility of labor.

Important as these legislative changes are, we do not mean to imply that the growth of guaranteed-wage plans should wait upon the reforms here suggested. On the contrary, in some lines of industry the guaranteed wage can be economically introduced under present conditions to the advantage of all parties. As the number of such industries grows, both employers and employees would have an increasing incentive to press for the needed legislation.

These legislative reforms, especially the integration with social security, would make it possible to strengthen such guaranteed-wage plans as may in any event be developed without waiting for new legislation; and they would encourage the spread of plans to other industries which (even with some kind of limitation of employer liability) might otherwise find it difficult to set up adequate and satisfactory programs.

ADDENDUM—DEPRESSION POLICY AND THE GUARANTEED WAGE

Note: This Addendum is presented as a basis for further discussion. It does not constitute a part of our Recommendations.

The analysis of previous chapters points to the conclusion that the guaranteed wage would be a weak rod to lean upon, by itself alone, as an anti-depression measure. Taken in conjunction with other measures—especially fiscal policy and social security—it can serve a useful purpose as a supplementary device. The guaranteed wage is not a cure for depressions. However, as we have seen in chapter V, it could perhaps serve its most useful purpose by overcoming seasonal or other irregularities of employment in industries operating in an economy with relatively high and stable aggregate demand.

THE FEAR OF DEPRESSION

But industry cannot safely assume that we shall in fact achieve in future a continuing high and stable level of demand for goods and services. It is precisely the fear of recurring major depressions that makes management reluctant to undertake commitments under the guaranteed wage. So long as the prospect of serious depressions remains as a major but incalculable risk, guaranteed-wage commitments must be rather severely restricted with respect to the liability involved. Such restrictions could be eased somewhat by building up in good times guaranteed-wage reserve funds.

Guaranteed-wage plans, privately financed, could reasonably be regarded as a manageable risk in a society freed from the fear of major depression. And even though this danger of recurring depressions must be faced, plans can, we believe, be devised along the lines discussed in chapter VI, which are made as "cyclone-proof" as possible. It now remains to consider whether some direct Government financial support of guaranteed wages might not be justified from two standpoints: (1) as a means of encouraging, in an unstable world, more widespread adoption by private industry of guaranteed wage plans; and (2) as a part of a rounded governmental anti-depression program.

ECONOMIC ASPECTS OF GOVERNMENT AID

The purely economic aspects of such Government support deserves to be considered on its own merits. In terms of political realism, so long as we are not prepared to accept direct Governmen contributions to social insurance programs (a policy adopted at the very inception of social insurance in England a generation ago), there is n likelihood that governmental grants-in-aid t guaranteed-wage plans will be acceptable. Socia insurance should be first in line for governmenta contributions from general revenues. This is tru among many reasons, partly because social insu ance is of universal application (within limi legally established) and does not apply only to su individual firms as may voluntarily choose to ta advantage of Government aid; and partly because social insurance provides a lower minimum income than is contemplated in most guaranteed-wage plans. Virtual universal coverage, taken in conjunction with the principle of a national minimum, commends social insurance as a program deserving direct Government financial aid and support. The case is less strong for the guaranteed wage. Until direct Government contributions to social insurance become a reality, it is probably somewhat utopian to discuss such aid for guaranteed wages. We should ourselves wish first to see direct Federal contributions to social insurance, thereby diminishing the deflationary effect of the regressive pay-roll taxes.

Nevertheless, the economics (apart from the politics) of support for the guaranteed wage deserves study. In terms of employment and anti-depression policy, there is much to be said for governmental grants-in-aid to guaranteed-wage

rograms. Indeed, even with respect to social in-
urance, Government contributions commend
hemselves in large part by reason of their implica-
ions with respect to full employment policy. The
ore social insurance is financed from progressive
come taxation, the more expansionist will the
rogram be.

Our exploratory discussion, in this addendum,
f partial governmental aid to the guaranteed
age, contingent upon emergency depression con-
tions, is very much in the spirit of many of the
ss controversial Government programs in other
heres. Federal insurance of bank deposits and
e capital salvage activities of the Reconstruction
nance Corporation are more or less analogous
stances. A third and more venerable precedent
that of central banking (Bank of England, the
deral Reserve System, etc.) whose function has
g been recognized as that of providing succor
"last resort" in times of crisis and depression.

Accordingly, we wish to raise the question
ether the program of financing guaranteed-
ge plans might not, to a degree, be incorporated
a comprehensive antidepression program, such
the Government may find itself called upon
undertake in periods of substantial unemploy-
nt. We believe that there are few, if any, who
bt that we shall in fact encounter more or less
lent fluctuations in business activity. A slump
e started can cumulate, under modern condi-
s, with incredible speed. The Federal Gov-
ment will not be able to stand by without under-
ng some positive program of action. In such
ods, governmental intervention in various di-
ions will be required in any event. In such
ods of crisis, therefore, governmental support
existing guaranteed-wage plans might provide
additional compensatory mechanism, thereby
cing somewhat the danger of unplanned and
eshift depression projects which otherwise are
y to be undertaken.

e believe, as we have repeatedly stated, that
ker income security can best be promoted by
gthening our already established system of
l security and by a comprehensive full em-
ment program designed to maintain a high
stable level of demand, production and em-
nent. Within this pattern, the guaranteed
can be made a useful supplementary device.
not something upon which we should embark
with a view to making it carry the whole load. It is not and cannot, we believe, be made the basic foundation of worker income security. But it can be made a significant part of a larger program.

To this end we explore below two highly tentative suggestions. We present them, not because we believe them currently to be within the range of practical politics, but to round out our economic analysis of the guaranteed wage, and to provide a starting point for further discussion. We suggest, in line with the discussion in Chapter V, that guaranteed-wage programs shall be wholly privately financed except in abnormal emergency periods of serious depression. We consider governmental aid to such plans only as a last resort measure, and as a part of a comprehensive attack on depression. We therefore explore two criteria indicating at what point in the depression phase of the cycle governmental aid might be invoked. The first is based on the level of profits of the firm in question; the second is based on the broad general level of business activity in the nation as a whole.

GOVERNMENTAL GRANT-IN-AID BASED ON PROFIT LEVELS OF FIRMS

Precisely in a condition of serious mass unemployment, government support for the continuation of guaranteed wage plans may be far more sensible than ill-designed antidepression measures, which in the absence of adequate planning are likely to be improvised. If a firm were assured that, upon a fall in the annual profits of the company to a small fraction of, say, the previous 5-year average, the Government would come to its support, the guaranteed wage plan might be saved from extinction; and what is more, many firms might be induced to establish guaranteed wages in good times, if they were assured that the Government would bear part of the costs contingent upon a deep depression when profits are low and losses are likely to be sustained. While it is true that special conditions may cause low profits for an individual firm even though general business activity is high, nevertheless experience shows that the profits of most firms fluctuate in close correlation with the cycle. A more complicated formula than the one we suggest below might be designed so as to combine both the criteria of (*a*) the firm's profits and (*b*) the general state of business.

Using the more simplified formula, however, let us suppose that the firm's profits have fallen to 30 percent (or some other appropriate figure) of the previous 5-year average. The Government might now undertake to contribute a grant-in-aid on a sliding scale basis, and increasing at a specified rate as profits continue to fall. The scale might, by way of illustration, be somewhat as follows:

Percent profits of previous 5-year average:	*Government share of guaranteed wage cost*
30	10
25	20
20	30
15	40
10	50

According to this formula, the Government would make an outright grant-in-aid to the current cost of the guaranteed wage plan (that is, to the guaranteed wage payments for workers declared by the company to be totally unemployed) beginning at 10 percent of the cost when profits fall to 30 percent of the previous 5-year average. The grant-in-aid might rise on a step-up basis as profits fall, finally reaching a maximum of 50 percent of the cost when profits fall to 10 percent or less. (A more precise formula is given below.)

In the next section we wish to discuss an alternative grant-in-aid procedure, based not on the profits of the particular firm, but on more general employment and business conditions in the Nation as a whole.[39]

GOVERNMENTAL FINANCIAL AID BASED ON LEVEL OF GROSS NATIONAL PRODUCT

The feasibility of a guaranteed wage, financed by private business, depends in large measure upon the kind of economy we shall have in the future—how violent will the fluctuations in the gross national product (GNP), employment and business activity be? To the extent that we succeed in narrowing the over-all range of fluctuation in the gross national product, the guaranteed wage becomes more feasible as a practical proposition. It is not feasible for guaranteed wage plans to include any substantial proportion of the total labor force in a society in which the gross national product fluctuates from 100 billion dollars to 50 billion dollars and then up to 200 billion dollars, a it actually did from 1929 to 1944. If, however, w could narrow the range of fluctuations in the gros national product to within 15 to 20 percent, i would become feasible to include in guarantee wage plans a substantial percentage of the tot labor force.

Grants-in-aid to guaranteed wage plans, onc the gross national product had fallen to a ce tain level—for example, to 85 percent of a ful employment level—might well be included as part, however modest, of a general antidepressi program. There would indeed be no guarant that the gross national product might not fa far below the level at which grants-in-aid wou begin. The program would amount to no co mitment with respect to full employment. presumably would mean that the Federal Gove ment would seek to promote full employment such politically acceptable measures as were av able. If these were reasonably successful, t gross national product might not fall to the le at which the grants-in-aid program would beg Up to this point, private business would be clusively responsible for the financing of s guaranteed wage plans as had voluntarily b put in operation.

The grant-in-aid could be stepped up if the G should continue to fall to lower levels. It is suggested, by way of illustration, that at 85 cent of a full employment GNP the grant-in might equal 25 percent of the current cost of guaranteed wage plan, i. e., 25 percent of amount actually paid out in wages to workers ered by the plans over and above the wage re ceived by workers for productive employmen together with unemployment compensation, du the year or period covered. If the GNP sh fall to 80 percent of the full employment lev, o below, the grant-in-aid might be raised to 50 cent of the cost. (A more precise formula is below.)

The criterion has been stated in terms o gross national product (GNP). In poi fact, the statistical calculation of the GN neither sufficiently current nor sufficiently p to provide the basis for a legal determinati the point at which a grant-in-aid would be

---

[39] Again it may be noted that a more complicated formula might be constructed which combines both criteria. On this basis, the governmental grant-in-aid would apply only when both general business conditions and the firm's profits had fallen to a certain level.

Some other statistical index which is precise and unequivocal, but which reflects fairly accurately the fluctuations in the gross national product, would have to be found. This is a matter which will require much careful study. Possibly the ratio of the number of workers receiving benefit payments under the unemployment insurance system to the total number of workers covered by the system might serve as an appropriate index. But the ratio should be applied so as to permit the entry of grants-in-aid (together with the step-up) as nearly as may be at some such points in the level of the gross national product as were indicated above.

It may be appropriate to note that the system of "compensatory payments" to farmers, advoated by some leading agricultural economists, ffers an interesting analogy to the suggestion to upport guaranteed wage plans at say 80 or 85 ercent of a "full employment" GNP or below. he agricultural "compensatory payments" plan, ery briefly, may be explained as follows:[40] The lan does not envisage any price controls or maret price supports. Assume that, as a result of depression, the market price of a given farm ommodity falls below 85 percent, say, of the preepression base. Assume the predepression price as $1 and it now falls to 60 cents. The Governent then undertakes to make compensatory payents to all farmers covering the difference tween the price actually received (60 cents) and cents, the guaranteed 85 percent of the predeession base. Such payments would provide nimum income security to farmers without inrfering with market forces. Prices would not raised. The commodity would not be "priced t of the market." But the farmer would be otected. And the compensatory payments uld be made by the Government at just the phase the cycle when it is important for the Governnt to find sensible, useful and justifiable outs for public expenditures—expenditures needed swell the diminishing income stream and stop cumulative collapse. As soon as recovery had ceeded to a point at which the price of the comdity had again reached 85 percent of the predepression base, the Government support would cease.

So also in the Government's support of the guaranteed wage; as soon as the GNP had recovered to 85 percent, say of the "full employment level," or the more specific and definitive index indicative of the degree of full employment (such as the ratio of current beneficiaries to the number of covered employees), the Government's support of established guaranteed wage plans would cease.

Our two suggestions involve one possible technical difficulty from which the agricultural compensatory payments plan is free. According to that plan, as farm prices drop from 86 percent of the predepression base down to 84 percent, nothing very drastic or discontinuous happens. Such a small change is accompanied by a commensurately small change in Government payments. All trouble of "discontinuous brackets" is avoided.

A MORE PRECISE FORMULA FOR EACH PROPOSAL

Our two suggestions seem to involve this technical difficulty. As a firm's profits suddenly fall to below the critical 30 percent level, or as GNP falls below the critical 85 percent level, suddenly and discontinuously the payments of the Federal Government go from nothing to the first bracket rates. This might give rise to troublesome litigation concerning the last decimal point of profits and GNP, and might even occasion deliberate efforts on the part of firms to cause their profits to fall!

These bracket difficulties can be avoided by making our grants-in-aid formula or table slightly more complex.

Thus, just as the Government financial share grows from 10 to 20 percent as profits fall from a 30 percent level to a 25 percent level, so we might arrange for the Government's share to rise gradually to the first 10 percent level, corresponding to the gradual fall in profits from 35 to 30 percent. Our exact formula might be something like the following:

(*a*) When percent of corporate profits to normal are above 35 percent—no Government aid.

(*b*) When percent of corporate profits to normal are less than 10 percent—Government aid equal to 50 percent of cost.

See Theodore W. Schultz, Agriculture in an Unstable Econ- (McGraw-Hill, 1945), pp. 220–235. This is a research study he Committee for Economic Development.

(*c*) Anywhere in between these two extremes we suggest the formula:

Percent of Government aid equals 70 minus (2 times the percent profits are of normal). This could be written as an equation as follows: $G=70-2P$, in which G is the percent of government aid and P is the percent which current profits are of normal profits.

This will be found to agree with the earlier table, and to avoid all bracket difficulty.

Similarly, our second formula based on GNP too might be as follows:

(a) Percent of GNP to full employment GNP above 90 percent—no Government aid.

(b) Percent of GNP to full employment GNP below 80 percent—Government aid equal to 50 percent of cost.

(c) Anywhere in between, the formula:

Percent of Government aid equals 450 minus (5 times the percent of GNP to full employment GNP). This could be written as an equation as follows: $G'=450-5P'$, in which G' is the percent of Government aid, and P' is the percent which the current GNP is of a full employment GNP.

VARIOUS ASPECTS OF THE GOVERNMENT AID PROGRAM

The two alternative grant-in-aid procedures which we have outlined would have a number of advantages. They would leave to collective bargaining, or to the employer alone in the absence of collective bargaining, the choice of whether or not to set up a guaranteed wage. Under the procedures here suggested, if a guaranteed wage plan is set up, the responsibility would devolve wholly upon private enterprise so long as (*a*) profits equalled 35 percent of the preceding 5 years, or (*b*) alternatively the gross national product did not fall below 90 (85 in the cruder formula) percent of a full employment product. The responsibility of the Government, up to this point, would not relate to the guaranteed wage, but rather to policies and programs that promote high business activity and high employment. Thus up to the point indicated the Government would not enter the picture at all with respect to the guaranteed wage programs so far as direct grants-in-aid are concerned.

Should, however, the situation with respect to individual businesses, or alternatively with respect to the economy as a whole, become serious, Government support in a variety of directions would sooner or later become necessary. Grants-in-aid for established guaranteed wage plans might well prove, in such circumstances, to be one measure which along with others might stop a deflationary spiral. There is increasingly general support for the thesis that early and vigorous support in many directions is less dangerous than delay, and is much to be preferred to risking all on any one policy. Reasonably early action may prevent a bad situation from getting worse.

Along with other antidepression measures, grants-in-aid to established guaranteed wage plans could help to put a cushion under a recession and prevent a further downward cumulative movement. The governmental grant-in-aid would involve the payment of funds into the income stream at a time when a Nation-wide depression is becoming really serious and needs to be stopped quickl and effectively. Planned public works and publi development projects can play an important role but many such projects cannot be timed quickl nor can they be adequate to check, without the ai of other measures, a cumulative downturn. Wha other programs may be necessary or desirable (in cluding tax adjustment) is not a matter whic properly comes under discussion here.

The plans discussed above would be automatica ly self-disciplinary. If the particular guarante wage plan introduced by an individual firm we overly cautious, it would be relatively ineffecti It would cost the firm very little, and by the sa token, it would cost the Government very littl and it would not satisfy labor. If the plan we overly ambitious, it would be costly to the fi up to the point at which the governmental gra in-aid would begin. This fact could be count upon to deter the company from setting up too a bitious a plan. If the firm had failed to m e good on its financial responsibilities under e plan, having dropped it entirely either in acco ance with the terms of the plan or in violation f these terms, the Government would have no e sponsibility to undertake the grant-in-aid. G ernment support would be accorded only s h plans as were actually in full operation at he point where grants-in-aid were scheduled to be in. As soon as the GNP again rose to a level above he oint indicated (or alternately profits rose) the Government support would cease.

On this basis every firm would know that any lan it might inaugurate would entail financial bligations to cover the entire cost of the guaran- eed wage for its covered employees only under easonably favorable conditions. In the event of nation-wide depression, it could rely upon Gov- rnment support. The business firm must indeed repare a plan which could reasonably be expected weather the storm up to the point at which gov- rnmental aid enters. And even then it must be repared to carry its share of the load. With such aranteed support, a firm could at least go farther th with respect to the proportion of its workers vered under the plan, and the percent of the full- ne wage guaranteed under the plan, than would the case without such support. How far each m is willing and able to go, under these condi- ns, is for it to determine for itself, either on its n volition or on the basis of collective bargain- with the union representing its employees. ere is no governmental compulsion. Any firm ich objects to a guaranteed wage is quite free go on without any plan. The governmental aid, ilable when conditions become difficult, is in- d an inducement, but it represents no compul- whatever to set up a guaranteed wage plan.

t will be noted that both of the suggested plans free of any element of unfair government e subsidization of one producer as compared to competitor. The Government contributes not nt toward the wage of any worker who is to degree productively employed.[41] Only after employer has declared a man completely unem- ed would the Government's aid be forthcom-

We do not wish to spell out the details, but umably such workers would be required to be stered with the unemployment insurance labor ange, and would be required to accept suitable native employment. Also, as discussed in ter VI, we suggest that unemployed workers ld be eligible for regular unemployment com- ation benefits, with the employer and government (under the guaranteed wage plan) making up the difference as specified in the guarantee.

To some extent these suggestions avoid the criticism that worker mobility will be adversely affected. The employer is still always left with an incentive—perhaps greater than that now existing under experience rating—to see that his laid-off workers accept suitable other employment. Nonetheless, we must expect that any system of almost 100-percent out-of-work compensation will weaken the employee's exertions to find another job and will make him more particular in accepting proffered alternative offers. This, however, is a basic difficulty of all guaranteed wages, whether completely privately financed or financed in part by the Government. Moreover, the loss of workers' incentives toward mobility is a much less serious economic problem at a time when there is widespread unemployment in all fields.

Since the Government comes in with financial aid when guaranteed workers are declared completely idle, there will always be some tendency for firms with guaranteed-wage plans to relax in their efforts to find low-productivity "fill-in" jobs for the workers to do in their own plants. As soon as the Government support came into operation, the costs incident to the guaranteed-wage plan in any firm would be carried in part by the Government and increasingly so as the depression deepened. There would thus be less incentive left for the firm to hold down costs by putting the largest possible number of covered employees to productive work or by securing work for them elsewhere. Nevertheless, there would always be some considerable incentive left, since the firm would cover at first all, then most, and finally at least 50 percent of, the cost.

The suggestion here made has the great merit that it could reasonably be expected that active full employment policies may be sufficiently successful so that the GNP would fall below 85 to 80 percent of the calculated "full employment" level only under relatively unusual circumstances, when the underlying factors were such as to threaten a really serious major depression. Under this suggestion one may hope that the Government guarantee would be invoked on any substantial scale only in periods of serious depression when vigorous measures to combat the downswing would, in any event, be necessary.

---

might be objected that an element of discrimination and ty is involved in the respect that government aid to the enance of wage income is applied only to workers who to be employed by firms with a guaranteed wage. This, er, we should not regard as decisive. What is important is rms be encouraged to introduce the guaranteed wage, and ll firms doing so shall be accorded equal treatment.

If the GNP has fallen below 80 percent of the "full employment level," the labor market would already be flooded with a large excess of applicants. Accordingly, from the social viewpoint, it would relieve the situation somewhat if the employees covered in guaranteed wage plans did not come on the market at all. Moreover, it might not help the general situation, under conditions of falling and low aggregate demand, for firms having guaranteed wage plans to enter the market with competing sidelines to give productive employment to some of their covered workers. Such action, in a period when total demand was sharply restricted, would contribute little, if at all, toward an expansion of aggregate demand. In such periods, taking on new lines by one firm probably supplants jobs elsewhere rather than adding to the total. In contrast, in periods of brisk demand and full employment, the elimination of seasonal and frictional unemployment would represent a net gain in social efficiency and total real income. If all workers were given steadier employment throughout the year, there would be a net gain in total output and total real income.

Neither the payment of compensatory supplements to farmers nor the payment of wages to idle workers covered by guaranteed wage plans represent the ideal situation. The ideal situation is one of sustained aggregate demand and full or high employment. But if, in fact, full employment policies prove to be only partially effective; or if wholly abnormal and unexpected factors emerge which cannot, in the short run, be coped with adequately, then compensatory payments to farmers and wage payments to covered workers under guaranteed wage plans may be valid, justifiable and helpful under the circumstances. The situation is a temporary one in which unusual and rather drastic measures may become necessary.

Financial aid to guaranteed wage plans is one channel of depression Government spending. In terms of the encroachment of Government activity on the private sector of the economy, it is a relatively conservative measure, since it involves only "transfer payments" to individuals, who in turn spend this money as they wish on the products of private industry. Thus, it is neither competitive with private industry nor "socialistic" in the sense of expanding the productive or collective consumption role of Government.

The problem is one of spending wisely, effectively, and equitably. Giving one favored group of workers 100-percent unemployment insurance while others receive limited partial benefits for a limited time, or no insurance benefits at all but only relief, cannot be defended as equity. From this point of view it might well be desirable to confine Government aid to plans with some sort of time limitation with respect to the period in which any one worker could continue to draw guaranteed wage payments. As a first line of defense against depression, relatively generous treatment of certain workers for a limited period can be defended. But it would be more important still to strengthen our general social security, relief and public works and development programs during the next serious depression. In the fina analysis, productive and useful employmen should be the goal.

The primary purpose of the suggestions described is to contribute in some measure to th general insurance against the social plague of dee depression. These suggestions, like all insuranc measures, would serve their purpose best if it neve became necessary to invoke them—if the syste always remained at high levels of employment ar general profits did not decline to low levels as result of adverse business conditions.

To conclude: An adequate full employme program would make governmental grants-in-a to guaranteed wages quite irrelevant as an an- depression device. But in the event, as is not i- probable, that we shall at times face rather - rious unemployment, such grants-in-aid could b a useful "last resort" instrument, to be applied al g with other measures as one part of a many-si d antidepression program. But while it is necess y to be prepared with antidepression policies, e must never lose sight of the positive program e- signed to provide continuing and high levels of useful and productive employment. Guaran ed wage plans are not adequate substitutes for o er public and private economic policies, even tho gh they may provide supplementary protec on against instability of production, employment nd income.

JBADDENDUM—COMMENTS ON THE HANSEN-SAMUELSON REPORT

Prof. J. M. Clark, Columbia University; Prof. Edward . Mason, Harvard University; Prof. Sumner H. lichter, Harvard University, together with Final Comients by Professors Hansen and Samuelson

1. COMMENTS BY J. M. CLARK

n general, the writer is in hearty agreement h the actual recommendations of the report, approves of their cautious and realistic char- er. He has, however, a feeling that in the body he discussion this caution is not aways fully ntained; and here and there, by tone and im- ation, an impression is conveyed of promise greater results, both in extent of voluntary ption and in effect on stabilization of employ- t, than are wholly consistent with the cautious acter of the actual recommendations. The uent qualifications which are introduced do entirely offset this optimistic impression. A major and minor comments follow.

rhaps the chief aspect which seems insuffi- ly recognized is the probability that if a anteed-wage plan were installed, covering all ost of the employees in an industry, the hiring ditional workers might involve such a heavy itment on the part of the employer that he l go slow about such hiring in times of active nd, with the result that employment might imply be stabilized, but the total reduced. would place a heavier burden on the high- yment program which, it is assumed, goes he wage program. It might be replied that, the wage program is voluntary, employers not be likely to undertake commitments so as to have this effect. This seems not fully ncing, since the pressure of organized labor d such programs may be very strong, and even develop quasicompulsory effects, im- employers toward assuming heavier com- nts than caution would dictate, in the light possibility here considered.

A second point is that, in view of the voluntary nature of the proposals, more attention might be given to modified plans, even if they may not so far have been proposed by interested parties. For example, it might be regarded as a defect of a simple guarantee from the standpoint of workers' incentives, that under it the worker would get paid no more for working the guaranteed amount of time than for working less. This could be avoided, and the employer's commitment be at the same time lightened, by a plan under which the worker would be paid full wages for full-time work, and something less though presumably more than half wages for idle time, down to some absolute minimum. The guarantee should properly be so figured as to give the worker something more than his unemployment benefits under social security, but less than full pay for idle time. This would avoid asking him, in effect, to work part of the time for nothing.

Methods of financing reserves deserve more discussion than is given them. In voluntary private plans, the employer would be under strong pressure to invest them productively, in private securities. Then when they had to be drawn on, in bad times, if these securities were thrown on the market in order to realize funds, the effect might be to accentuate depression, offsetting the alleviating effects of the distribution of the proceeds to the workers. This dilemma seems to deserve consideration; it might be avoided by some credit arrangement.

A fourth point concerns the effect of stabilization on the productivity of workers. Here I agree with the general conclusion that the net effect is likely to be favorable, and my reservation is largely concerned with the timing of the effect. Experience seems to show that when bad times threaten, workers work harder, and increase their output. It is when a lay-off does not immediately impend that workers are urged to make their jobs last as long as possible, by restraining output. This is complicated by the effect of reduced output in increasing indirect costs per unit produced, so that total labor cost per unit of product may rise, or output per man-hour fall, on account of this latter factor, which has nothing to do with the attitude of the workers, or how well they work. Dr. Julius Hirsch, in a paper delivered before the American Economic Association, January 25, 1947, attempted to separate these two effects on productivity, and found that the kind that registers the efficiency of the workers behaved in the way I have indicated.

A fifth point concerns the incentive the employer has to make capital outlays in slack times, because of the lower prices then available. This is an incentive which must, in the nature of the case, stop far short of full stabilization, since it is only if demand is slack that prices are likely to come down. A single industry could get this gain, in an economy where the rest were still following the usual practice and concentrating their capital outlays in active times. But if capital-expansion in dull times became the standard practice, the price-incentive would be destroyed. Further, it is still true that, the longer the employer waits, before a revival is expected, the shorter is the time during which his capital is tied up, idle, and the risk he runs of installing equipment that does not embody the latest improvements. Therefore, this incentive seems to be subject to a much heavier discount than is indicated in the report.

The incentives of the employer, arising from the combination of a guaranteed wage with social security, seem to deserve some analysis. It seems to be implied that the employer could, at his option, limit his liability to the excess of the guaranteed wage above the regular unemployment-benefits, by declaring his worker unemployed, and leaving him to find another job if one is offered. It appears that this would, in practice, involve him in little likelihood of losing a worker through the worker's getting another job, because it seems only natural that the employment office would give priority to job-seekers who were not covered by guaranteed-wage plans—this on the assumption that such plans are voluntary, and have not become universal. Then if social security pays the worker, for example, 55 percent of his regular wages, it would pay the employer to let his worker go onto social security if the only work the employer could find for him to do were worth less than 55 percent of full wages. If it were worth more, it would pay the employer to keep him.

In this connection, the discussion of the loss, or cost, of unemployment, gives the impression that it is the worker's full wage, or its equivalent, that is lost, though elsewhere it is noted that the best employment that is available in depressed times is likely to be something that is not worth the full amount of the standard wage.

Other minor points might be mentioned. Th report suggests the maintenance of adequate tota demand as a goal, and takes the position that a fair approach to attainment of this goal is a prerequisite to any general successful adoption of guaranteed-wage plans. But no ways and means are suggested for a full employment program nor is any estimate made of the probable degree of success of any measures of the sort which might be adopted. This is perhaps a matter in the public view of the President's committee of advisers, set up under the Full Employment Act; but this committee does not seem as yet to have filled this gap.

In chapter II, section 1, the report states: "It is perhaps not too hard to imagine an economic system in which the wage contract with all employees was more nearly like that with executives and white-collar workers than like the present prevailing mode of wage payment and tenure." I agree that present modes of wage payment show a remarkable lack of imaginative adaptation to the facts of modern industry. But if this means that all workers could be put on a basis of fixed salary, it is hard for me to imagine this under a system of private enterprise, in view of what seems to be the admitted fact that private enterprise is inescapably subject to some degree of fluctuation, and probably a fairly substantial degree, even with the best that can be done toward stabilization. It is easier for me to imagine a system of cooperatives in which the workers are their own employers, and hire capital for a secure return; but in that case they would necessarily take the risks that now fall on equity capital. Their salaries might be fixed, but they would be combined with sharing of profits and losses.

In conclusion, let me repeat that the actual
ecommendations of the report appear to deserve
pproval.

2. COMMENTS BY EDWARD S. MASON

Messrs. Hansen and Samuelson rightly em-
hasize the wide range of variation in types of
uaranteed wage plans, and in employee coverage
nd employer commitments involved. Taking
is range into account it is possible to conceive a
tuation in which guaranteed wage plans would
widely used without any appreciable effect on
orker security or on the functioning of the econ-
ny. This would be so if the only workers cov-
ed were those the employer could reasonably ex-
ct to retain at the lowest expected rate of oper-
ions, and if his commitment were subject to fre-
ent revision. Under these circumstances the
ceptance of the plan would offer no special in-
cement to the employer to explore ways and
ans of stabilizing employment; it would offer
appreciable increase in the employees' security
tenure; and it is difficult to see how it would
any way significantly alter work incentives, in-
ne distribution, or, in general, the functioning
the economy. Even a wide acceptance of such
ranteed wage plans would have the same negli-
le effect as minimium-wage-rate legislation set-
g rates substantially below the market mini-
m.

he problem becomes interesting and important
y if plans are adopted committing the em-
yer to wage payments he would not otherwise
ume and offering a greater measure of security
employees than they would otherwise enjoy.
ler what circumstances would the employer be
ly voluntarily to accept such a commitment?
uaranteed wage plan might be adopted if it
nised to give the employer the pick of the labor
ket, if it were judged to offer new and import-
work incentives, and if possibilities existed for
ning the disadvantages of a new overhead com-
nent by stabilizing operations through diversi-
ion or otherwise.

ese are all real possibilities. But it must be
gnized (*a*) that the advantages of the plan
nd largely on its not being extensively
ted by competitors in the labor market, and
hat the stabilization effects are mainly
ed to the firm and have no appreciable advantages for business cycle stability in the whole economy. If all—or even a large number of—employers accepted additional commitments under guaranteed wage plans in the expectation that their selection of employees would be improved or that their operations could be stabilized by diversification, the expectations of a large percentage would be unavoidably disappointed. It must also be recognized that the advantages of a guaranteed wage plan, which may be real enough as long as the number of such plans is small, may create additional disadvantages for the firms not adapting to the scheme.

Some possibilities for improving efficiency or stabilizing employment, which are net for the economy as a whole, may exist, but these possibilities would seem to be slight. It is possible that the productivity of workers already employed may be increased by the additional security offered by a guaranteed wage plan. Hansen and Samuelson consider this possibility and, in my view, rightly discount its certainty or quantitative importance. There is also the possibility that the adoption of guaranteed wage plans might lead to the merging of operations which are complementary over time (e. g., coal and ice). Although this would make no contribution to over-all business cycle stability, it might lessen the number of necessary changes in employment. Again, however, the main effects of diversification by particular firms might often be to increase the instability of operations of other firms. All this is simply an elaboration of the point that the main influences on stability for the whole economy lie outside the control of single firms.

Recognizing this fact, the authors raise the question whether it is possible for employers in unstable industries by acting together to contribute to stability. Although this might be done independently of guaranteed wage plans, it is possible that the common introduction of such plans in an industry could provide an incentive for stabilization otherwise lacking. The question is whether the causes of instability lying outside the control of individual firms may be to some extent within the control of an industry acting as a unit. Commenting on the notorious instability of employment and output in the automobile industry, Hansen and Samuelson emphasize that, to the extent that this instability is cyclical, the search for remedies must look in other directions than toward guaranteed wage plans. "But," they say, " it is not too much to hope for, and to ask of management and labor, that measures be taken and practices be altered to moderate the incidence of irregular and seasonal employment and of economic idleness. This may require many far-sweeping changes in the organization of the industry; increases in inventories and storage facilities, limitations on undue coddling of consumers' desires with respect to modification of style and model changes, perhaps acceptance of lower hourly wage rates in exchange for higher annual earnings."

It is possible that action of this sort might make a substantial contribution to stability of employment in automobile production. It is probable that the suggested changes would increase costs and prices to consumers. It seems to me unlikely that standardization, for example, could be brought about without collusive action or a degree of cooperation among competitors beyond the limits permitted by present public policy. Perhaps existing policy should be changed. But this question raises issues of considerably greater importance than those involved in guaranteed wage plans. It seems doubtful whether the stabilization possibilities lying outside the control of individual firms, but within the control of the industry, are of sufficient importance, in themselves, to justify the degree of industry planning—with the concomitant necessity of Government supervision—it would be necessary to achieve in order to realize these possibilities. In any case the question opens vistas too broad for adequate consideration here.

If the scope of guaranteed wage plans is primarily determined by profit considerations and if industry-wide stabilization operations (which might broaden the opportunities for such plans) are excluded, it does not seem probable that a system of wage guarantees will be widely adopted, at least in an economy as unstable as the American economy has historically been. Yet the most important and interesting questions that Hansen and Samuelson discuss assume a substantial coverage of the economy by guaranteed wage plans. It is possible that, if accompanied by effective counter-cyclical stabilization measures, the coverage of wage guarantees would in fact be substantially increased. This will be discussed presently. The important questions referred to above have to do with the changes in aggregate demand and its stabilization over the cycle and with the effect of the increase in overhead costs involved in guaranteed wage plans on pricing policy.

With respect to the first question, the authors point out that the level of aggregate demand is not likely to be raised by guarantee of wages unless such guarantees transfer incomes from profits to wages and unless these transfers increase marginal propensities to consume. They are properly dubious about such effects. Even if wage guarantees clearly worked in this direction, it would still be difficult to see why employers would voluntarily accede to them unless we suppose a general understanding and agreement among businessmen tha their own long-run best interests are served by th higher and more stable level of employment tha the acceptance of a lower rate of profit might b supposed to entail. It seems probable that th "Keynesian revolution" has not yet been th successful.

The effect of guaranteed wages as a stabilizer aggregate demand over the cycle depends pr marily on the method of financing. If reserv accumulated in good times are paid out in ba some stabilizing effect will be produced. But u less firms can be supposed to undertake comm ments of a character and magnitude that wou substantially increase business risks this effect is bound to be small. The authors recognize this fully and their tentative support, in the append of Government grants-in-aid to guaranteed wage plans, stems from this recognition. In part the case for grants-in-aid depends on the expanded coverage by guaranteed wage plans that might be expected to follow from the adoption of grants-in part, the case rests in the familiar argument for deficit spending in depression. To the extent that deficit spending is the remedy, this type of spending has to be justified as against other claimants. The main advantage, stressed by Hansen and Samuelson—though not in these words—is that it can be "built in" to a functioning economic system rather than being hastily improvised as so many kinds of Government depression spending are. Although a number of practical difficulties (a ing to do mainly with inequality of treatme

ifferent firms and industries) are obvious, the
iggestion merits careful attention.

With respect to the consequences of guaranteed
age plans for price behavior, the conclusion of the
ithors appears to be that the conversion of vari-
le into overhead costs would probably have only
slight effect. While this conversion might, un-
r competitive pricing conditions, be expected to
ad to greater variation in prices over the cycle,
ey think that, in industries likely to adopt guar-
teed wage plans, market structures are such as to
vor the use of "full cost" pricing policies. If,
erefore, it can be shown that such plans increase
e "full cost" per unit of operations over the
cle, the effect on prices might be considerable.
gardless of the extent to which firms may or
y not undertake full cost pricing, it is clear
t any substantial increase in the relative im-
rtance of overhead costs will accentuate the dan-
to profits to be expected from competitive price
ting. The tendency to stabilize prices, by agree-
nt or otherwise, will thereby be encouraged.
ofar as the effects are limited to an increased
istance to price declines in depression, the
ter would agree with Hansen and Samuelson
t the weight of modern opinion considers
h effects to be contributory to stability in the
le economy. If "cooperation" among competi-
is seriously promoted through a widespread
ption of guaranteed wage plans, it is improb-
, however, that joint action would be limited
esistance against depression price declines. It
early possible that the substantial conversion
ariable into overhead cost inherent in these
s might, through the increased incentives it
s to industry-wide planning, considerably re-
the scope of desirable competitive adjustment
e economy. It must be admitted, however,
this question is highly speculative.

is the view of the authors of this report that
anteed wage plans are unlikely to play a sig-
nt role except within the framework of an
ive national policy directed toward the main-
ce of a high level of employment. In the un-
e American economy of the recent past, the
ntages to the employer of lay-offs on short
e are of such importance as to make it improb-
that more than a small number of firms will
such plans. Furthermore, as already em-
zed, the advantage of these plans to the firms adopting them are likely to be substantial only if the number remains small.

If an effective national employment policy can be assumed, the situation is different. Even under these circumstances, however, the authors caution against exaggerating the merits of a guaranteed wage program. They state explicitly that "if it ever had to come to a choice between guaranteed wages and other important depression and anticyclical public and private policies, * * * then it would be guaranteed wages that would have to be rejected." It is a great strength of the report, in the eyes of this reviewer, that the relative merits of guaranteed wages as against other reform programs are carefully weighed. In a situation in which the stimulus to reform is strictly limited it is important to establish a carefully considered priority of objectives.

If a high level of employment were expected to be maintained the coverage of voluntarily initiated guaranteed wage plans might, for a number of reasons, be very substantial. A much larger number of firms could apply such plans to a much larger percentage of their employees without an appreciable increase in business risk. Employers, faced with a continually serious problem of recruiting and maintaining a labor force would find that the relative merit of guaranteed wage plans as compared with the privilege of lay-off at short notice had measurably increased. Although the authors find, even in the recent past, little evidence that instability of employment is compensated by higher hourly earnings in unstable industries, it might be expected that with a high and sustained level of employment this condition would be rectified by competitive forces. If this were so, firms, even in unstable industries, would probably find it possible to adopt guaranteed wage plans without incurring a large increase in labor costs.

On the other hand, although the coverage might be much larger, the importance of worker insecurity under such circumstances would be much less. The authors, nevertheless, believe that guaranteed wages might make an important contribution to stabilizing "seasonal and other short rhythms in production and by equitably allocating the economic burden of the residual amount of unavoidable idleness and unemployment." By shifting the burden of seasonal and short-term unemployment to the shoulders of employers, the incentive to integrate operations having complementary time periods and to undertake industry-wide planning to increase stability of output would certainly be increased.

As we have seen, there are real disadvantages involved in this process that must be set off against the advantages. In addition the substantial lessening or disappearance of worker incentives to seek other employment during slack periods would handicap short-term adjustment. As so often is the case in the area of economic policy, there seems to be a real conflict between security and efficiency involved in this question of guaranteed wages. It is not obvious to the writer that, even if the maintenance of a high level of employment could be assumed, the probable disadvantages of a large-scale acceptance of guaranteed wages would not outweigh the advantages.

3. COMMENTS BY SUMNER H. SLICHTER

The guaranteed wage is a proposal to impose an additional liability upon business owners. Although the proposals vary substantially, they have one common characteristic—the liability to pay for labor which would not otherwise be used is one which would have to be met in the main, not in periods of expansion and optimism, but in periods of contraction and pessimism. Furthermore, the amount of the liability in most industries would be conjectural in the extreme because the severity of business cycles cannot be foreseen. This second characteristic could be altered somewhat by modifications in the plans. In fact some existing wage or employment guarantee plans provide ways for reducing the employer's liability in the event of severe depression. Finally, the liability is of such nature that it is increased in amount by the very conditions which decrease the business enterprise's ability to meet it out of current income.

Hansen and Samuelson consider two types of plans: (1) Pay-as-you-go plans, and (2) reserve plans in which, however, the liability is not limited to the amount in the reserve funds. I believe that a third type of plan should be examined, namely reserve plans with liability limited to the amount in the reserve fund. Hansen and Samuelson make a suggestion closely akin to this in their recommendations. They suggest that the liability of employers be limited. They do not, however, suggest that it be limited to the amount in the reserve funds.

Three basic questions are raised by wage guarantee plans: (1) Their effect upon the distribution of income; (2) their effect upon the utilization of resources; and (3) their effect upon the business cycle and the growth of industry. In general I agree with Hansen and Samuelson with respect to the effect of wage guarantees upon the distribution of income and the utilization of resources. With much of their analysis of the cyclical effects of wage guarantees I am in agreement. There are, however, some points of difference. Consequently, I have confined these notes to a discussion of the cyclical effects of wage guarantee plans.

Before I start this discussion I wish to cal attention to the fact that wage guarantee plan would require during boom times a larger sprea than would otherwise exist between the price o labor and the prices of goods. This would b necessary because of the risk that employers woul be compelled during slack periods to make wag payments which are not covered by the value the services rendered. The greater spread betwee wages and prices during boom times might accomplished either by a rise in prices or by slower rise in wages. It is uncertain which these ways would be more important in bringi about the greater spread between wages and pric If one assumes that the amplitude of boom a depression is unchanged, the distribution of i come over the period of the whole cycle would n be significantly changed. Wage earners and co sumers would fare worse than now during boo periods and better than now during depressio; business owners would fare better than now d ing booms and worse during depressions.

Pay-as-you-go wage guarantees

Pay-as-you-go wage guarantees would acc tuate business recessions. This result would oc for several reasons. One effect of pay-as-you plans would be to stimulate managements to strengthen the liquid position of their enterpr at the first signs of contraction in business. B ness concerns, of course, now do the same thi— especially enterprises which have short-term d or other important liabilities to meet. The efforts of business concerns to protect themse against the drop in business aggravate the dec he pursuit of liquidity by enterprises during riods of contraction ought to be discouraged ther than encouraged. Pay-as-you-go wage arantee plans, however, would encourage it. All this amounts to saying that most pay-as-you-go ins could not be kept strictly on a pay-as-you-go sis. Even if assets were not earmarked and led "reserve funds," they would be accumulated inst the liability imposed by the wage guaran- plans. Furthermore, under the so-called "pay- you-go plan," the accumulation would occur t when it would do the most harm.

second effect of wage guarantees (whether pay- ou-go or not) would be to make cost-price rela- ships during depressions more unfavorable n they would be in the absence of guaranteed es. Since workers would have to be paid ther they produced or not, managements would illing to produce goods which have to be sold rices which would not cover cost of production puted by conventional methods. Hence wage antees would depress prices and make prices lower relative to costs than they would other- be. The effects of wage guarantees upon pro- ion would not probably be very great in oligo- tic industries. It would, however, be an im- nt influence in industries where there are small competitors, particularly the "soft s" industries.

e unfavorable cost-price relationships thus ced by wage guarantees and the resulting on liquid assets would put managements un- reater pressure than ever to cut expenditures aintenance, replacement, research, and prod- evelopment. It would also discourage the ng of new enterprises. Even in severe de- ons there are many thousands of business each year and substantial expenditures on l goods for replacement, reduction of costs, pansion by established enterprises.

cial mention should be made of the effect -as-you-go plans upon the operation of the system during depressions. The liabilities ed by these plans would make banks more o reduce outstanding credits to enterprises to the liability and less inclined to extend edits. Thus, pay-as-you-go plans would be rful influence in enforcing a contraction in d deposits.

The effect of pay-as-you-go plans upon the demand for labor and upon wages would be unfavorable. Naturally enterprises which had wage guarantee plans that were about to expire would seek to anticipate their orders for goods after the expiration of the plans by making large quantities of goods before the expiration of the plans. Thus plans which were about to expire would build up inventories of partly manufactured and manufactured goods that would prove troublesome. Certainly the fact that this process was going on and that inventories were overhanging the market would discourage both the starting of new enterprises and the execution of many projects by existing concerns. The fact that employers who had built up large inventories under the stimulus of wage guarantees would be in an unusually strong bargaining position in negotiating renewals of their contracts with unions would introduce uncertainty into the whole wage structure of the industries affected.

These several difficulties might not be serious if the depression were mild, but the existence of a large number of pay-as-you-go plans would increase the difficulty of keeping depressions mild. If the depression were severe, pay-as-you-go wage guarantee plans would appear to be well designed to make it more severe and to weaken the bargaining position of unions in renewing contracts which expire during the depression.

Wage guarantee plans with liability not limited to the amount in the reserve funds

Wage guarantee plans financed out of reserve funds but with the liability not limited to the amounts in the reserve might mitigate depressions provided business managers felt quite confident that the depression would be mild and that the reserve funds would be more than adequate. The disbursement of the reserve funds by raising the propensity to consume would limit the effect of a given drop in investment upon incomes and upon employment. Furthermore, if businessmen were quite sure that reserve funds would be more than adequate, the disbursement of the funds would make managements less inclined to cut postponable expenditures, such as outlays for maintenance and replacements and some expenditures for expansion.

All of the above assumes that managements are governed by the belief that reserve funds would be ample. This would certainly not be true in severe or even moderately severe depressions. As it became apparent that the depression was going to be deeper than businessmen had anticipated, wage guarantee plans financed out of reserve funds would produce more and more the same unfortunate effects as pay-as-you-go plans. Furthermore, even in mild depressions wage guarantee plans with the liability of employers not limited to the amount in the reserve funds would produce some unfavorable effects. Some firms would be new and would have had no opportunity to accumulate reserve funds; some would have had a bad employment record. Hence, at least a few firms would be led by their liabilities under wage guarantees to strive for greater liquidity than they would otherwise have sought. Many more firms, as a result of their liabilities, would be viewed as unattractive credit risks by banks and would be forced by the reduction of their lines of credit to curtail expenditures on maintenance and replacements and possibly to liquidate inventories at distress prices.

Reserves with liability limited to the amount in the reserves

Guaranteed wage plans financed by reserves and with the employer's liability limited to the amount in the reserves would make a moderate, but nevertheless important, contribution to the stabilization of employment. The limitation of the employer's liability to the amount in the reserve fund would prevent the wage guarantee from stimulating employers to attempt to increase their liquid assets during periods of contraction. Thus wage guarantee plans of this third type would not have unfavorable effects upon the expenditures of business concerns for maintenance, replacements, and expansion. On the contrary, the reserves would have two favorable effects upon the level of employment. First, by increasing the propensity to consume it would diminish the unfavorable effect of a given drop in investment upon income and hence upon employment. Second, by limiting the losses of business enterprises and improving the terms on which they could liquidate their inventories, the disbursement of the reserve funds would make managements less inclined to cut expenditures on maintenance and replacements and to suspend the execution of plans for expansion.

Would not the favorable effects of the disbursement of reserves during periods of contraction be offset by deflationary effects from the accumulation of reserves during periods of expansion? I do not think so. In the first place, favorable effects of the disbursements of reserves during periods of depression would cause prospective investors to take a slightly more favorable view of investment opportunities. In the second place, the accumulation of reserves would make investment-seeking funds available on slightly more favorable terms.

Would not the accumulation of reserves during periods of expansion limit expansion by raising the propensity to save? There are some majo uncertainties in the effect of the accumulation o reserves during periods of expansion. It is quit conceivable, as I shall point out presently, that th accumulation of reserves would have inflationar repercussions on the credit system. More likel is the possibility that the accumulation of reserv would modify the character of booms by limitin the expansion of credit and the rise in price Booms are periods when incomes rise because t planned savings of individuals and business ente prises fail to meet the demand for investment-seeking funds. The impatient demand for investment-seeking funds causes the rise of income be accelerated by the expansion of credit and u ally by a rise in prices and often by speculation in inventories. The rise in prices limits the favorable effect upon employment from a given rise n expenditures. Furthermore, after this type of expansion has gone on for some time, it creates market conditions which discourage business enterprises from immediately executing long-term investment plans. Hence the nature of booms under the modern credit system limits the capacity of the economy to utilize investment opportunities created by technological change. Were expansions financed to some extent out of reserve funds rather than by the expansion of credit, the expansion would probably go farther and the expansion would consist to a greater extent in a rise in employment and to a lesser extent in a rise in prices. Hence, although the effect of the accumulation of reserve funds would be deflationary in terms of prices, it would not necessarily be deflationary in terms of employment.

There is a real possibility, however, that the ac-umulation of reserve funds will stimulate the xpansion of credit. The reserve funds would un-loubtedly be invested largely in the short-term bligations of the Government. The buying of hese obligations by the reserve funds would inter-ere with the ability of the banks to maintain the olume of their investments in short-term govern-ients. At times when the business outlook is re-irded as favorable, banks are averse to per-iitting a drop in their earning assets. Hence, ilure of banks to replace their short-term govern-ents would undoubtedly lead them to be more iterprising and aggressive in putting money to ork in commercial loans and term loans. As an termath to the unfortunate inflationary effects the expansion of bank credit during the boom, ould be the even more unfortunate deflationary ects produced by the repayment of these loans in riods of contraction.

This analysis of the probable effects of different pes of wage guarantees should not be concluded thout pointing out that the judgment of the obable effects of the plan must be predicated on estimates of the number of workers whom h plans may cover and to whom they might ke an important difference. About one-fourth the workforce would not be included because y are self-employed rather than employees. substantial proportion of the workforce, n if covered, would get no appreciable efit from guaranteed wage plans because y are virtually assured of indefinite tenure er present conditions. These include nearly employees in the public service, a substantial iber of employees in the industries and oc-itions with little seasonal or cyclical fluctua-s, and a substantial number of additional loyees who are protected from seasonal or ical lay-offs because of seniority rules. A third e group of employees work under conditions h would make a 12 months' guarantee (or a 6 months' and, in many cases, a 3 months' antee) impractical. These include people in mittent employments such as most people in onstruction industry, the amusement industry, acation industry, and the large number of le who enter the labor market for a few weeks during each year. As a very rough guess I would estimate that about one-fifth or one-fourth of the entire workforce are employed under such conditions that a guarantee would appreciably affect their annual income. This does not mean a guarantee might not be a useful device in the case of this fraction of the workforce. Nevertheless, it does indicate, however, that the possible favorable effects upon the total volume of consumer income from all sources would be quite limited. At the best, the incomes of people receiving only about one-sixth of all consumer incomes would be directly augmented to an appreciable extent by an annual wage guarantee.

4. FINAL COMMENTS

By Alvin H. Hansen and Paul A. Samuelson

The comments of Professors Clark, Mason, and Slichter are particularly welcome and valuable because the complex imponderable factors involved in an economic evaluation of guaranteed wages cannot definitively be appraised by one team of investigators. Accordingly, we wish to confine our reaction to their comments to a few of the more important points where there still remain some substantive difference in analysis and emphasis.

1. *Depressant effects upon investment due to higher wage costs.*—All three writers emphasize—as we do too (pp. 29–31)—that guaranteed wage commitments may act as an appreciable deterrent to business investment. Taken by itself, this is a damning consideration. But it should not be taken by itself, since there may also be a favorable effect upon income when wages are maintained.

There is a universal dilemma to be faced here, which goes far beyond the guaranteed wage. Compulsory workmen's compensation legislation, minimum wages and conditions of work, collective bargaining and pressure for higher wages, social security legislation—all of these can be thought of simply as a hampering drag upon "venture capital." But they each also have favorable aspects from the standpoint of social and individual welfare, equity, and income maintenance. Realistically, they are probably here to stay; our private enterprise system cannot shirk their challenge. Nor, taking the long view, is it likely that it can hold the line against their further extension over future decades.

Fortunately, the trend of economists' opinions over the last two decades does not appear to be definitely toward the view that the favorable income and purchasing power side of the wage question is overbalanced by the unfavorable investment effects. But to discuss this further would take us far afield.

2. *Anticyclical effects of reserve financing.*—Because of our stated belief that all reserve funds should be invested in Government bonds or equivalents, and because it is now definitely unfashionable to invest pension funds in the private securities of the employing company, we did not feel it necessary to discuss the problems raised by such private modes of financing. High-grade Government bonds tend to go to a premium in bad times. For this reason, and because the Federal Reserve authorities have ample powers to stabilize their marketability, such securities offer the ideal medium for reserve financing.

Professor Slichter expresses concern that guaranteed wage reserve funds will purchase Government securities at the expense of the banking system; in the process excess reserves would be created; thereby private loan expansion would be encouraged. This represents an instance of our statement (p. 33) that the deflationary impact of boom-time reserve accumulation may be partially offset by an easing of interest rates and capital availability. At worst, this could only be a partial offset: Partial because interest rates weaken only in consequence of a final decline in total income. Even this partial perversity can be easily offset by having the Federal Reserve authorities do what they always should do with respect to actual or potential excess reserves during inflationary boom times.

We cannot wholly acquiesce in Professor Slichter's appraisal of the absence of deflationary influences resulting from boom-time reserve accumulations. The reasoning of his preceding paragraph seems to hold that an increase of corporate saving—for that is precisely what reserve financing means—is, by itself, an "expansionary" factor. In our view it could be so only in the following inverted sense: A deliberate deflationary policy which successfully offsets an inflationary boom-time situation may prolong the duration of prosperity and full employment. Only in this sense, could a "deflationary" policy be "expansionary"; and this does not deny its deflationary character or differ with the accepted view that reserve financing is anticyclical. Moreover, only in those special boom periods where employment and purchasing power tend to be "more than full," would such a deflationary policy be desirable.

During depressions, replacement expenditures of corporations often fall below depreciatio charges; they often fall by more than the total o corporation losses. Consequently, there is a "run off" on fixed assets which will to some degree mod erate the need of the corporation to rely complete upon previously funded reserves. Guarantee wages may also be paid at the expense of depressio dividends. But as we pointed out (on p. 29), i the absence of funded reserves, there may still some harmful effects of guaranteed wage paymen upon the ability of the firm to maintain some of i depression gross investment, and this is in li with Professor Slichter's discussion.

3. *Guaranteed wage plans with alternati limitations.*—Professor Clark (p. 53) and Profe sor Slichter (p. 60) have each suggested a mo fied guaranteed wage plan. There are an infin range of such programs and it is useful to expl a variety of possibilities. In our Report we ha suggested the need in many fields of some limi tion upon employers' guaranteed wage liabilit In particular our recommendation No. 2 in cha VI suggested the advisability of the type of lim tion of liability developed in Mr. Latimer's fi report (whereby the liability of any employe a given period is limited to some agreed-upon centage of his total guaranted pay roll).

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., June 24, 1947.

The Secretary of Labor:

I have the honor to transmit herewith the report on the extent of collective bargaining and union recognition for 1946. The study is based on an analysis of approximately 15,000 collective-bargaining agreements, as well as other source materials on employment, union membership, and other data available to the Bureau of Labor Statistics. The report was prepared by the staff of the Collective Bargaining Division, under the general supervision of Harold S. Roberts, in the Bureau's Industrial Relations Branch, Boris Stern, Chief. Philomena Marquardt was in immediate charge of assembling the information.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Extent of Collective Bargaining and Union Recognition, 1946[1]

Union-Agreement Coverage

Approximately 14.8 million workers were employed under conditions determined by written collective-bargaining agreements in 1946, an increase of a million workers compared with 1945. The workers covered by agreement represent 48 percent of the 31 million[2] engaged in occupations in which the unions have been organizing and endeavoring to obtain written agreements. The percentage covered was the same in the previous year, but fewer workers—approximately 29 million—were eligible for agreement coverage in 1945. Nonmanufacturing industries accounted for much of the increase in employees eligible for agreement coverage.

About 7.9 million production workers in manufacturing were covered by union agreements in 1946 (69 percent of those employed) compared to 8 million (67 percent) a year earlier. In the nonmanufacturing industries 6.9 million workers, or 35 percent of the potentials were employed under union agreements. Part of the decrease in total coverage in the manufacturing industries can be accounted for by changes in employment in such industries as aircraft and shipbuilding, in which a large proportion of the workers are covered by union agreement. In the nonmanufacturing industries the increase in the number of workers can be accounted for by higher employment in such industries as construction, in which the proportion of workers covered by collective bargaining is very high.

The extent of union agreement coverage in the various manufacturing and nonmanufacturing industries is shown in table 1. Because each group covers a range of 20 percent, it is possible for the proportion of covered workers within an industry to increase several percent and still remain within the same group. During 1946 the percentage of workers covered by agreements in the dairy products industry increased enough to bring it from the 1–19 percent into the 20–39 percent category. Chemicals, excluding rayon yarn and the paper products industries moved from the 20–39 percent into the 40–59 percent group. Canning and preserving foods, dyeing and finishing textiles, and leather gloves increased in the proportion covered so that they shifted from the 40–59 percent to the 60–79 percent column. Moving from the 60–79 percent into the 80–100 percent group were the electrical machinery and the rayon yarn industries.

---

[1] For similar data for previous years, see Monthly Labor Review, April 1946, April 1945, April 1944, Feb- uary 1943, May 1942, and March 1939.

[2] This estimate of 31 million includes all wage and salary workers except those in executive, managerial, nd some professional positions, but excludes all self-employed, domestic workers, agricultural wage workers n farms employing less than six persons, Federal and State Government employees, teachers, and elected r appointed officials in local governments.

It should be noted that the number of workers covered by union agreements is not the same as union nembership. Except under closed or union-shop conditions, agreements cover nonmembers as well as nembers employed within the given bargaining unit. On the other hand, some union members may be orking in unorganized plants and many civil-service employees and teachers are members of unions but re not employed under the terms of bilateral written agreements.

TABLE 1.—*Proportion of wage earners under union agreements in 1946*

MANUFACTURING INDUSTRIES

80–100 percent	60–79 percent	40–59 percent	20–39 percent	1–19 percent
Agricultural equipment. Aircraft and parts. Aluminum. Automobiles and parts. Breweries. Carpets and rugs, wool. Cement. Clocks and watches. Clothing, men's. Clothing, women's. Electrical machinery. Furs and fur garments. Glass and glassware. Leather tanning. Meat packing. Newspaper printing and publishing. Nonferrous metals and products, except those listed. Rayon yarn. Rubber. Shipbuilding. Steel, basic. Sugar.	Book and job printing and publishing. Coal products. Canning and preserving foods. Dyeing and finishing textiles. Gloves, leather. Machinery, except agricultural equipment and electrical machinery. Millinery and hats. Paper and pulp. Petroleum refining. Railroad equipment. Steel products. Tobacco. Woolen and worsted textiles.	Baking. Chemicals, excluding rayon yarn. Flour and other grain products. Furniture. Hosiery. Jewelry and silverware. Knit goods. Leather, luggage, handbags, novelties. Lumber. Paper products. Pottery, including chinaware. Shoes, cut stock and findings. Stone and clay products, except pottery.	Beverages, nonalcoholic. Confectionery products. Cotton textiles. Dairy products. Silk and rayon textiles.	(None.)

NONMANUFACTURING INDUSTRIES

80–100 percent	60–79 percent	40–59 percent	20–39 percent	1–19 percent
Actors and musicians. Airline pilots and mechanics. Bus and streetcar, local. Coal mining. Construction. Longshoring. Maritime. Metal mining. Motion-picture production. Railroads. Telegraph. Trucking, local and intercity.	Radio technicians. Theater—stage hands, motion-picture operators.	Bus lines, intercity. Light and power. Newspaper offices. Telephone.	Barber shops. Building servicing and maintenance. Cleaning and dyeing. Crude petroleum and natural gas. Fishing. Hotels and restaurants. Laundries. Nonmetallic mining and quarrying. Taxicabs.	Agriculture.[1] Beauty shops. Clerical and pro fessional, exclud ing transport tion, commun cation, theater and newspaper Retail and whol sale trade.

[1] Less than 1 percent.

Types of Union Recognition

EXTENT OF COVERAGE

Approximately 4.8 million workers were covered by closed and union shop with preferential hiring provisions in 1946, compared to 4.25 millions in 1945. Union shop clauses, without preference in hiring, were specified for almost 2.6 million workers in 1946 and 2 million in 1945. The number of workers covered by maintenance of membership decreased from more than 3.9 million in 1945 to 3.6 million in 1946.

Table 2 indicates the changes in the proportion of workers under each type of union recognition from 1941 through 1946. During the war there was a major shift from sole bargaining and bargaining for members only to maintenance of membership. The 1946 figures indicate a trend away from the latter type, and to the union or closed shop.

TABLE 2.—*Changes in union recognition in the United States, 1941–46*

Item	1941	1942	1943	1944	1945	1946
Eligible for union-agreement coverage:						
Number (in millions)	[1] 35	31	31	30.25	29	31.2
Percentage under agreement	30	40	45	47	48	48
	Percentage distribution [2]					
Workers under agreements providing for—						
Closed shop	40	45	30	28	30	33
Union shop			20	18	15	17
Maintenance of membership	(3)	15	20	27	29	25
Preferential hiring	(3)	5	2	2	3	3
Other [4]	(3)	35	28	25	23	22
Total	--------	100	100	100	100	100

[1] This figure is not comparable with the number listed as eligible for other years since it includes all sal-ed workers and all government employees. The figure which would be comparable is 31 million.

[2] Percentages not strictly comparable, year by year, because of slight changes in volume of employment ring the period.

[3] No data.

[4] No membership or hiring requirements are mentioned in these agreements, which have clauses speci-ng sole bargaining, maintenance of union dues, and bargaining for members only.

Table 3 lists the industries in which at least half of the workers who e under agreement are covered by the type of union recognition ecified.

A few industries (such as shipbuilding and iron and steel products) ich were listed in the 1945 report do not appear this year because percent of the workers in those industries are no longer covered by y one type of recognition clause. Carpets and rugs and woolen d worsted were both listed under maintenance of membership in 45 but in 1946 over half of the workers in those industries who were ered by union agreements were under union-shop provisions.

The most marked change has taken place in the automobile industry. In 1945 over half of the covered workers had maintenance-of-membership provisions, in 1946 a little over 10 percent had such provisions, while a third were covered by union-shop requirements, a fourth by sole-bargaining arrangements, and another fourth by maintenance-of-union-dues requirements.

The proportion of workers under the different types of union security for a selected group of industries is shown in table 4, while the approximate number of workers in each of the major census groups for manufacturing and the totals for nonmanufacturing are given in table 5.

TABLE 3.—*Industries with 50 percent or more of the workers under agreement covered by specified types of clauses*

MANUFACTURING INDUSTRIES

Closed or union shop with preferential hiring	Union shop	Maintenance of membership	Preferential hiring	Sole bargaining
Baking. Breweries. Canning and preserving foods. Clothing, men's. Clothing, women's. Dyeing and finishing textiles. Gloves, leather. Glass containers. Hosiery. Printing and publishing. Shoes, cut stock and findings.	Carpets and rugs, wool. Flat glass. Knit goods. Paper and allied products. Sugar, beet. Woolen and worsted textiles.	Aircraft and parts. Cigarettes and tobacco. Chemicals. Cotton textiles. Electrical machinery. Machinery, except electrical. Meat packing. Nonferrous metals. Petroleum refining. Rubber. Steel, basic.	Pottery.	Cement. Sugar cane.

NONMANUFACTURING INDUSTRIES

Construction. Trucking and warehousing.	Coal mining.	Crude petroleum and natural gas. Metal mining. Public utilities, electric light and power, water and gas. Telegraph.	Longshoring. Maritime.	Railroads. Telephone.

DEFINITIONS

Closed shop

Under this type of union recognition all employees must be members of the union at the time of hiring and they must remain members in good standing during their period of employment. The following is the simplest form of a closed-shop provision:

> The employer shall employ none but members in good standing in the union. All employees shall remain members in good standing as a condition of continued employment.

Hiring through the union, unless it is unable to supply the required number of workers within a given period, is required under most o the closed-shop agreements and those employees who are hired through other procedures must join the union before they start to work.

Union shop

Workers employed under a union-shop agreement need not be union members when hired, but they must join the union within a specified time, usually 30 to 60 days, and remain members during the period of employment. A characteristic clause setting up a union shop generally reads:

> All present employees not on the excluded list (outside the bargaining unit) who are not now members of the union, must become members within 30 days after the signing of this agreement. All persons employed, after this date, must become members of the union within 30 days after date of their employment. All employees will remain members of the union in good standing as defined by the constitution and bylaws of the union as a condition of employment for the duration of this agreement.

Union shop with preferential hiring

When the union-shop agreement specifies that union members shall be given preference in hiring or that the hiring shall be done through the union, the effect is very much the same as the closed-shop agreement.

> When the company is in need of a new employee, the union shall have the first opportunity to supply such employee. If the union shall be unable to supply such employee within 1 week, or if the union waives the right to supply such employees, the company may hire any person it desires.
>
> Any new employees hired by the company who are not already members of the union, shall become members of the union within 2 weeks of the date of their employment. Only members in good standing of the union shall continue in the employ of the company.

Modified union shop

In some cases the union shop is modified so that those who were employed before the union shop was established are not required to become union members. This type of union security is sometimes referred to as a modified shop.

> (a) All employees hired after the date of execution of this agreement must, after a 6-week probationary period, become and remain members of the Union in ood standing as a condition of continued employment. In individual cases the mployer shall have the opportunity of negotiating with the union with respect to longer probationary period.
>
> (b) It is agreed that present employees, who have not and do not desire to join he union, need not do so as a condition to their continued employment with the ompany. It is agreed that all employees who are members of the union, or who ay become members of the union, shall remain members in good standing during e life of this agreement.

Maintenance of membership

This type of union security requires that all employees who are members of the union a specified time after the agreement is signed and all who later join the union, must remain members in good standing for the duration of the agreement. Following the pattern of the maintenance of membership clauses established by the National War Labor Board, most of the agreements with this type of union-security clause provide for a 15-day period during which members may withdraw from the union if they do not wish to remain members during the life of the agreement.

> It is agreed that all employees who, 15 days after the signing of this agreement, namely, [date] are members of the union in good standing in accordance with the constitution and bylaws of the union, and all employees who thereafter, become members of the union, shall, as a condition of employment, continue to remain members in good standing as long as the union specified above remains the collective bargaining agent.
>
> Members of the union who are delinquent in dues payments shall pay all dues before they shall be permitted to avail themselves of the 15-day escape period provided for above.
>
> Members of the union in good standing for the purpose of this provision shall be all persons who are members in good standing as of [date] or who subsequently become members and have not resigned or withdrawn and so notified the union in writing prior to [date].

Maintenance of union dues

During 1946 a few agreements covering workers employed by large companies which had specified maintenance of membership in 1945 were modified, to provide sole bargaining with the check-off of union dues for all union members as a condition of employment. Clauses of this type (which specify this form of irrevocable check-off) are found in agreements negotiated with the General Motors Corp., the Goodrich Tire and Rubber Co., Akron, the International Harvester Co., East Moline, Ill., the Western Electric Co., and Yale & Towne. An example of this maintenance of union-dues clause is as follows:

> All employees who, 15 days after the beginning of the first pay roll week following the date of this agreement [date], are members of the union in good standing in accordance with its constitution and bylaws, and all employees who become members after that date, shall, as a condition of employment authorize the company for the duration of this agreement to deduct from their pay and transmit to the union an amount equivalent to their union dues as currently established by the union in accordance with its constitution and bylaws.

Preferential hiring

No union membership is required under this type of clause but union members must be hired if available. When the union cannot supply workers, the employer may hire nonmembers and they are not required to join the union as a condition of employment.

Members of the union shall have all of the work pertaining to the rigging up of ships and the coaling of same, and the discharging and loading of all cargoes including mail, ships' stores and baggage. When the union cannot furnish a sufficient number of men to perform the work in a satisfactory manner, then the employer may employ such other men as are available.

Sole bargaining

Under some agreements no requirement for union membership or for hiring through the union is specified. The union is the sole bargaining agent for all employees and negotiates the agreement covering all workers in the bargaining unit whether they are members of the union or not.

The company recognizes union No. ——— as the exclusive bargaining agency for all production and maintenance employees of the company, exclusive of executive, administrative, office, clerical employees * * * and all supervisory employees with the authority to hire, discharge, discipline, or effectively recommend changes in the status of employees as to factory wage rates, hours, and working conditions.

Members only

A few agreements stipulate that the union shall act as bargaining agent for its members only, and the agreement does not cover other workers.

> The employer recognizes the ——— union as the collective bargaining agency for its production and maintenance employees who are members of the union, at the employer's ——— works and mine.

TABLE 5.—*Approximate number of workers covered in 1946, by the type of union security listed*

Industry	Closed shop	Union shop with preferential hiring	Union shop	Membership maintenance
Manufacturing	1,275,000	950.000	1,506,000	3,031.000

Miscellaneous	15,000	12,000	20,000	40,000
Nonmanufacturing: Total, all groups [1]	2,082,000	547,000	1,091,000	664,000

[1] Included in this group are employees in construction, trucking, warehousing, services, clerical, sales and professional occupations, mining, transportation, communications, and public utilities.

Check-Off Arrangements

EXTENT OF COVERAGE

Approximately 6 million workers (41 percent of all under union agreements) were covered by some form of check-off provisions in 1946. This is an increase of close to three-quarters of a million from the 1945 total. Automatic deduction of dues was specified for a little over half of these workers while the others specified check-off of union dues only for employees who give the employer an individual written authorization. Some of these may be withdrawn at any time; others remain in effect for the life of the agreement.

In the manufacturing industries 4.7 million workers (61 percent had their dues checked off compared to the 4 million (about 50 percent) in 1945 The number of nonmanufacturing workers covere by check-off arrangements remained at about 1.3 million for 194 but this was not quite 20 percent of the workers under agreement; i 1945 with only 13.8 million under agreement the same number workers covered brought the proportion to 24 percent.

Changes in check-off arrangements from 1942 through 1946 are given in table 6 and they show a gradual increase in the number of workers covered by such provisions. Table 7 lists the industries which have at least half of the workers under agreement covered by one type of check-off. A few industries listed for 1945, such as chemicals, steel products, and men's clothing, no longer have 50 percent of the covered workers under a single type of check-off.

The proportion of workers under agreement by type of check-off for selected industries is given in table 8, while the approximate number of workers covered by check-off in 1946 for the major manufacturing industries as for nonmanufacturing is shown in table 9. Table 8 also shows the proportion of workers under agreement by each type of check-off during 1946 for manufacturing and nonmanufacturing industries. Below are definitions of the two types of check-off and examples of union agreement clauses providing for each.

TABLE 6.—*Changes in check-off arrangements in the United States, 1941–46*

DEFINITIONS

Automatic check-off

Many agreements specify that the employer shall deduct the union dues from the pay of all union members. In addition they may specify that initiation fees and assessments shall be checked off.

The company will deduct from the pay of each employee covered by this agreement all union initiation fees, dues, and assessments.

Voluntary check-off

A number of agreements specify that the employer shall check off union dues or assessments only for those employees who sign individual authorization. In most cases the employee may withdraw his authorization whenever he wishes.

The company agrees that any member of local——— may, upon written instructions to the company with a copy to local———, request the company to deduct his union dues from his pay check once each month and the company agrees that such collected dues will be turned over monthly to the financial secretary of local——— with full accounting thereof. It is understood that any union member may rescind such deduction instructions at any time, provided the company is given written 30 days' notice with a copy to local——— on a form provided for that purpose. Unless rescinded, authorization for deduction of all dues shall continue for the duration of this agreement.

Bureau of Labor Statistics,
Washington, D. C., May 4, 1947.

The Secretary of Labor:

I have the honor to transmit herewith the annual report on union wages and hours in the building trades, as of July 1, 1946.

This report was prepared in the Bureau's Wage Analysis Branch by Donald H. Gerrish assisted by James P. Corkery and Herbert M. Abowitz. The section on the Wage Adjustment Board was prepared by Dorothy K. Newman.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Union Wages and Hours in the Building Trades, July 1, 1946

Summary

HOURLY union wage rates for building-trades journeymen averaged $1.79 an hour on July 1, 1946, and for helpers and laborers $1.14. Bricklayers showed the highest average ($2.06 an hour). Between 1945 and 1946 over 95 percent of the workers received a wage-rate increase of at least 10 percent. Among the 75 cities studied, Charlotte, N. C., had the greatest average increase in journeyman rates (17 percent), and Charleston, S. C., had the most substantial advance for helpers and laborers (42 percent).

Straight-time weekly hours, averaging 39.1 for journeymen and 39.5 for helpers and laborers, represented about a 1-percent reduction during the year. Approximately three-fifths of the journeymen and one-fourth of the helpers received double-time rates for overtime; about 90 percent of both groups received double pay for Sunday work.

Scope and Method of Study

This article is based on effective union scales (as of July 1, 1946). These are defined as the minimum wage rates or maximum schedule of hours agreed upon through collective bargaining between employers and trade-unions. Rates in excess of the agreed minimum may be paid to union members because of long service, special qualifications, or for personal or other reasons. These premium rates were not used in the preparation of this report. Field representatives of the Bureau obtained 2,759 quotations of scales covering 509,331 journeymen and 117,290 helpers employed in 75 cities ranging in size from 40,000 to over 1,000,000.

The 1946 survey took place during the short interval when all wage and price controls were suspended by virtue of the Presidential veto of the bill extending the Price Control Act.[1] In general, the scales reported by the union officials as effective on July 1 had received prior approval of the Wage Adjustment Board for the building construction industry. For 64 cases in which higher rates were reported on July 1 than had been previously authorized, the subsequent restoration of controls legalized the higher rates in over 40 percent of the instances and rolled back the remainder to lower levels. Comparison of the last authorized rates with those reported on July 1 indicated that had wage controls been operative on the survey date, hourly average wage rates for journeymen and helpers would have been about 0.7 percent and 1.0 percent less, respectively. It is recognized, however, that the 64 cases are too few to permit any adequate generalization.

---

[1] H. R. 6042 (79th Cong., 2d sess.) was vetoed June 29, 1946. This bill also provided for the extension of the Stabilization Act.

Union Hourly Wage Rates

TREND OF UNION WAGE RATES, 1907–46 [2]

The annual increase of more than 11 percent in rate of pay, shown on July 1, 1946, was the largest percentage change recorded over a single year since 1920 (table 1). Practically all this advance took place after VJ-day. During the war and the early reconversion period, the effectiveness of the Wage Adjustment Board in stabilizing wage rates for the building construction industry is evidenced by the following facts: Between 1941 and 1945 hourly rates in this industry increased only 10 percent (amounting to about 14 cents an hour), in contrast with a 35-percent rise (about 18 cents an hour) for a comparable period in World War I (1916–19). From the time wage controls were adopted in July 1942 until July 1945, building hourly rates rose only slightly less than 4 percent.

---

[2] The Bureau has computed an index series with the year 1939 as a base for measuring changes in scales from year to year. This index series, rather than the actual average of rates in this and previous reports, should be used to determine the trend of hourly wage rates because of changes in coverage and shifts in union membership between two periods.
